Entropy power inequality for the Rényi entropy

Sergey G. Bobkov and Gennadiy P. Chistyakov

Abstract—The classical entropy power inequality is extended to the Rényi entropy. We also discuss the question of the existence of the entropy for sums of independent random variables.

Index Terms—Rényi entropy; entropy power inequality.

I. INTRODUCTION

Given a random vector $X$ in the Euclidean space $\mathbb{R}^d$ with density $p$, the (differential) Rényi entropy of order $\alpha > 1$ is defined by

$$h_\alpha(X) = -\frac{1}{\alpha - 1} \log \int_{\mathbb{R}^d} p(x)^\alpha \, dx.$$ 

Introduce the corresponding Rényi entropy power

$$N_\alpha(X) = \exp \left[ \frac{2}{d} h_\alpha(X) \right] = \left( \int_{\mathbb{R}^d} p(x)^\alpha \, dx \right)^{-\frac{2}{d} \frac{1}{\alpha - 1}}.$$ 

Here the ratio $\frac{2}{d}$ in the exponent makes this functional to be homogeneous of order 2 (although sometimes a different constant is used, cf. e.g. [16], or it is just omitted).

Both quantities are well-defined and may take the values $-\infty \leq h_\alpha(X) < \infty$ and $0 \leq N_\alpha(X) < \infty$. If the distribution of $X$ is not absolutely continuous with respect to Lebesgue measure on $\mathbb{R}^d$, put $h_\alpha(X) = -\infty$ and $N_\alpha(X) = 0$.

As $\alpha$ increases, the entropies $\alpha \to h_\alpha(X)$ do not increase, so the limits

$$h_1(X) = \lim_{\alpha \to 1} h_\alpha(X), \quad N_1(X) = \lim_{\alpha \to 1} N_\alpha(X)$$

exist. Moreover, if $\int_{\mathbb{R}^d} p(x)^\alpha \, dx < \infty$, for some $\alpha > 1$, we arrive at the usual Shannon entropy $h_1 = h$ and the entropy power $N_1 = N$, where

$$h(X) = -\int_{\mathbb{R}^d} p(x) \log p(x) \, dx, \quad N(X) = \exp \left[ \frac{2}{d} h(X) \right].$$

On the other side, as $\alpha \to \infty$, we deal with the functions of the maximum of the density,

$$h_\infty(X) = \lim_{\alpha \to \infty} h_\alpha(X) = \log \frac{1}{M(X)},$$

$$N_\infty(X) = \lim_{\alpha \to \infty} N_\alpha(X) = M^{-\frac{2}{d}}(X),$$

where

$$M(X) = \text{ess} \sup_x p(x).$$

These functionals contain an important information about the distributions and possess a number of remarkable properties. For example, all $N_\alpha$ are affine invariant, i.e.,

$$N_\alpha(TX) = N_\alpha(X),$$

where $T : \mathbb{R}^d \to \mathbb{R}^d$ is an arbitrary linear operator preserving the Lebesgue measure ($|\det(T)| = 1$). In addition, they are translation invariant and, as was mentioned, homogeneous of order 2, i.e., for all $h \in \mathbb{R}^d$, $\lambda \in \mathbb{R}$,

$$N_\alpha(X + h) = N_\alpha(X), \quad N_\alpha(\lambda X) = \lambda^2 N_\alpha(X).$$

These two identities resemble a similar property of the variance functional.

As another general property, one should mention monotonicity under convolutions ([5]): We have

$$N_\alpha(X + Y) \geq N_\alpha(X),$$

whenever $X$ and $Y$ are independent. (Since we assume that $\alpha > 1$, this property follows from the convexity of the power function $t \to t^\alpha$). In other words, the Rényi entropy may only increase when adding an independent summand.

If one restricts to the usual case $\alpha = 1$, the monotonicity property may considerably be sharpened. Namely, the classical entropy power inequality indicates that

$$N(X + Y) \geq N(X) + N(Y),$$

(1)

cf. [17], [6], [10], [11], [14]. More generally, if $X_1, \ldots, X_n$ are independent random vectors in $\mathbb{R}^d$,

$$N(X_1 + \cdots + X_n) \geq \sum_{k=1}^n N(X_k).$$

(2)

One may therefore wonder how to extend this inequality to other values of $\alpha$. The point is that with the current definition of $N_\alpha$, the last two relations do not hold in general for the Rényi powers.

Example. Let $d = 1$ and let $X$ and $Y$ be independent random variables uniformly distributed in the interval $(0, 1)$. They have density $p(x) = 1_{0 < x < 1}$, so

$$N_\alpha(X) = 1, \quad \text{for all } \alpha \geq 1.$$ 

The sum $X + Y$ has the triangle distribution with density $1 - |1 - x|$ ($0 < x < 2$), so,

$$N_\alpha(X + Y) = \left( \int_0^2 (1 - |1 - x|)^\alpha \, dx \right)^{-\frac{2}{d} \frac{1}{\alpha - 1}}$$

$$= \left( \frac{\alpha + 1}{2} \right)^{-\frac{1}{\alpha - 1}}.$$
In particular, $N_3(X + Y) = 2$. Since $\alpha \to N_\alpha(X + Y)$ is decreasing, we conclude that
\[ N_\alpha(X + Y) \geq N_\alpha(X) + N_\alpha(Y), \quad \text{if and only if } 1 \leq \alpha \leq 3. \]

A similar conclusion can be made, when $X$ and $Y$ are independent random vectors uniformly distributed in the cube $(0, 1)^d$.

Nevertheless, one can show that, at the expense of a universal factor in front of the sum, the inequality (2) does hold for all $N_\alpha$ regardless of the number of the summands. More precisely, we prove:

**Theorem I.1.** If $X_1, \ldots, X_n$ are independent random vectors in $\mathbb{R}^d$, then
\[ N_\alpha(X_1 + \cdots + X_n) \geq c_\alpha \sum_{k=1}^n N_\alpha(X_k), \quad (3) \]
where $c_\alpha > 0$ depends on $\alpha$, only. Moreover, one may take
\[ c_\alpha = \frac{1}{e^{\alpha^{1-\alpha}}} \quad (\alpha > 1). \]

Hence, we have an effect which is similar to the usual entropy power: The Rényi entropy power increases at least linearly with respect to the summands. Note, however, that in contrast with (1)-(2), the inequality (3) cannot be reduced to the case of two summands, since an application of the induction argument would lead to a logarithmically decaying constant (with respect to $n$).

As a function of $\alpha$, the constants $c_\alpha$ decrease from 1 to $\frac{1}{e}$. This can already be seen from the identity
\[ \frac{1}{2\pi} N_\alpha(Z) = \alpha^{-\frac{1}{\alpha}}, \]
where $Z$ is a standard normal random variable. Hence, in the limit as $\alpha \to 1$, (3) contains the entropy power inequality (2).

In the other limit, as $\alpha \to \infty$, we get a similar inequality for the maximum of the density,
\[ M^{-\frac{2}{\alpha}}(X_1 + \cdots + X_n) \geq \frac{1}{e} \sum_{k=1}^n M^{-\frac{2}{\alpha}}(X_k). \]

This particular case has recently been considered in [7]. Moreover, combining some delicate results due to Rogozin [15] and Ball [1], in dimension $d = 1$ one may replace $\frac{1}{2}$ with constant $\frac{1}{2}$. It is best possible and is attained for $n = 2$ in the above mentioned example of the uniform distribution on $(0, 1)$.

Anyhow, in all cases,
\[ N_\alpha(X_1 + \cdots + X_n) \geq \frac{1}{e} \sum_{k=1}^n N_\alpha(X_k). \]

Let us also state another immediate consequence of Theorem I.1, which makes use of the homogeneity of the Rényi power.

**Corollary I.2.** If the independent random vectors $X_1, \ldots, X_n$ satisfy $N_\alpha(X_k) \geq N$, for all $k \leq n$, then
\[ N_\alpha(\theta_1 X_1 + \cdots + \theta_n X_n) \geq \frac{1}{e} N, \]
wherever $\theta_1^2 + \cdots + \theta_n^2 = 1$.

Note that the Rényi entropy and the corresponding entropy power are also defined and treated for the parameter values $0 < \alpha < 1$ (with the same formula). However, we do not know, whether or not an analog of Theorem I.1 remains to hold in this case. Theorem I.1 can be proved with the argument which is similar to the one of Lieb [12], who applied the Young inequality with sharp constants when deriving the entropy power inequality (1). The general case $\alpha > 1$ is however a bit more delicate and requires to work with convolutions of an increasing number of densities.

In the next section we remind a basic general result, and then specialize it to convolutions of probability densities (Section III). Final steps of the proof of Theorem I.1 are made in Section IV. Then we turn to the classical case $\alpha = 1$ (Sections V-VI) to address the following question which seems to be ignored in the literature: Under what most general assumptions should one formulate the entropy power inequality (1)?

## II. Sharp Young’s inequality

For $1 \leq \nu \leq \infty$, we denote by $L^\nu$ the space of all measurable functions $u$ on $\mathbb{R}^d$ with finite norm
\[ \|u\|_\nu = \left( \int_{\mathbb{R}^d} |u(x)|^\nu \, dx \right)^{1/\nu}. \]

In particular, $\|u\|_\infty = \text{ess sup}_x |u(x)|$. Define the conjugate power
\[ \nu' = \frac{\nu}{\nu - 1}, \]
so that $\frac{1}{\nu} + \frac{1}{\nu'} = 1$.

The Young inequality with sharp constants was discovered by Beckner [4], cf. also [8], [2]; it is stated below for several functions following [4].

**Theorem II.1.** Assume that $u_k \in L^{\nu_k}$ ($k = 1, \ldots, n$), and let $\sum_{k=1}^n \frac{1}{\nu_k} = \frac{1}{\nu'}$. If $\nu_k \nu' \geq 1$, then the convolution $u = u_1 * \cdots * u_n$ belongs to $L^{\nu'}$ and has the norm
\[ \|u\|_{\nu'} \leq A \|u_1\|_{\nu_1} \cdots \|u_n\|_{\nu_n}. \]

For example, when $\nu = \nu' = 2$, the basic condition on the parameters becomes
\[ \sum_{k=1}^n \frac{1}{\nu_k} = 1. \]

If $\nu_1 = 2$, then all remaining values must be $\nu_k = 1$, so that $\nu_k = \infty$ ($k = 2, \ldots, n$). Hence, in general, the $L^2$-norm of $u$ cannot be estimated from above in terms of the $L^2$-norms of $u_k$. Nevertheless, this is possible, if we additionally know the $L^1$-norms of $u_k$. Such a conclusion can be made, in particular, when dealing with probability densities on $\mathbb{R}^d$. 
III. THE CASE OF DENSITIES

Here we develop one application of Theorem II.1 involving (probability) densities on $\mathbb{R}^d$.

First note that, given a measurable function $u \geq 0$ on a measure space $(\Omega, \mu)$, by Hölder’s inequality, there is a family of relations

$$\int u^{(1-\theta)p+\theta q} \, d\mu \leq \left( \int u^p \, d\mu \right)^{1-\theta} \left( \int u^q \, d\mu \right)^{\theta},$$

holding whenever $p, q \geq 0, 0 \leq \theta \leq 1$. In particular, taking $p = 1$ and assuming that $\int u \, d\mu = 1$, we have

$$\int u^{(1-\theta)+\theta q} \, d\mu \leq \left( \int u^q \, d\mu \right)^{\theta}, \quad q \geq 0, \quad 0 \leq \theta \leq 1. \tag{4}$$

Let $q = \alpha > 1$ and $\nu \geq 1$. Then $(1-\theta) + \theta \alpha = \nu \iff \theta = \frac{\nu - 1}{\alpha - 1}$. Hence, if $1 \leq \nu \leq \alpha$,

$$\int u^{\nu} \, d\mu \leq \left( \int u^q \, d\mu \right)^{\frac{\nu - 1}{\alpha - 1}}.$$

Let us state this particular case of (4) separately by raising the above inequality to the power $1/\nu$ and assuming that $\mu$ is the Lebesgue measure on $\Omega = \mathbb{R}^d$. As before, $\nu' = \frac{\nu}{\nu - 1}$.

**Lemma III.1.** For any density $p$ on $\mathbb{R}^d$,

$$\|p\|_\nu \leq \left[ \left( \int_{\mathbb{R}^d} p(x)^\alpha \, dx \right)^{-\frac{1}{\alpha - 1}} \right]^{1/\nu'} \quad (1 \leq \nu \leq \alpha, \quad \alpha > 1).$$

Next, given densities $p_k$ on $\mathbb{R}^d$ ($k = 1, \ldots, n$), consider the convolution $p = p_1 * \cdots * p_n$. By Theorem II.1, for $1 \leq \nu_k \leq \infty, \alpha > 1$, we have

$$\|p\|_\alpha \leq A \|p_1\|_{\nu_1} \cdots \|p_n\|_{\nu_n} \tag{5}$$

as long as

$$\sum_{k=1}^n \frac{1}{\nu_k} = \frac{1}{\alpha'} = 1 - \frac{1}{\alpha}, \tag{6}$$

and with constant

$$A = \left(\frac{\alpha_1 \cdots \alpha_n}{\alpha} \right)^{d/2}. \tag{7}$$

The condition (6) requires that $\frac{1}{\nu_k} = 1 - \frac{1}{\alpha'} \leq 1 - \frac{1}{\alpha}$ which is equivalent to $1 \leq \nu_k \leq \alpha$. Hence, one may apply Lemma III.1 to $p_k, \nu_k$ and $\alpha$, and get

$$\|p_k\|_{\nu_k} \leq \left[ \left( \int_{\mathbb{R}^d} p(x)^\alpha \, dx \right)^{-\frac{1}{\alpha - 1}} \right]^{1/\nu_k}. \tag{8}$$

Combining (5) with (8), we obtain that

$$\|p\|_\alpha \leq A \prod_{k=1}^n \left[ \left( \int_{\mathbb{R}^d} p_k(x)^\alpha \, dx \right)^{-\frac{1}{\alpha - 1}} \right]^{1/\nu_k}$$

$$= A \prod_{k=1}^n \|p_k\|_{\alpha'}/\nu'_k \tag{9}$$

with constant described in (7).

Now we see that in contrast with Theorem II.1, for any $\alpha > 1$, the $L^\alpha$-norm of $p$ can indeed be estimated in terms of the $L^{\alpha'}$-norms of $p_k$. Moreover, the equality (6) provides some freedom in choosing $\nu_k$ which may be used to make (9) as sharp as possible.

But, first let us restate the inequality (9) in terms of the Rényi power. If a random vector $X$ in $\mathbb{R}^d$ has density $p$,

$$\|p\|_\alpha = \left[ \left( \int_{\mathbb{R}^d} p(x)^\alpha \, dx \right)^{\frac{1}{\alpha - 1}} \right]^{1/\alpha'} = \frac{N_\alpha(X)}{\nu_k^{\alpha'}}.$$

Hence, raising (9) to the power $-\frac{2\alpha'}{d}$, we arrive at the inequality with a constant which does not depend on $d$.

**Corollary III.2.** If $X_1, \ldots, X_n$ are independent random vectors in $\mathbb{R}^d$, then for the sum $S_n = X_1 + \cdots + X_n$ we have

$$N_\alpha(S_n) \geq B \prod_{k=1}^n (N_\alpha(X_k))^{\frac{\alpha'}{\nu_k}},$$

whenever (6) holds with $\nu_k \geq 1, \alpha > 1$, and with constant

$$B = (A_{\nu_1} \cdots A_{\nu_n} A_{\alpha'})^{-\alpha'}. \tag{11}$$

Strictly speaking, the application of Lemma III.1 still requires that $X_k$ have densities. This assumption may, however, be removed. Indeed, in the case when the distribution of any of $X_k$ is not absolutely continuous, then $N_\alpha(X_k) = 0$, and (10) is fulfilled automatically.

IV. PROOF OF THEOREM I.1

One can try to optimize the inequality (10) over $\nu_k$, but an appropriate (in general non-optimal) choice may considerably simplify this inequality. Put $t_k = \frac{\alpha'}{\nu_k}$, so that, by Corollary III.2,

$$N_\alpha(S_n) \geq B \prod_{k=1}^n N_\alpha^{t_k}(X_k), \tag{12}$$

or equivalently,

$$\log N_\alpha(S_n) \geq \sum_{k=1}^n t_k \log N_\alpha(X_k) + \log B. \tag{13}$$

Here, according to the condition (6), $t_k$’s may be arbitrary positive numbers such that $t_1 + \cdots + t_n = 1$.

To work with (12)-(13), in view of the homogeneity of the functional $N_\alpha$, we may and do assume that

$$\sum_{k=1}^n N_\alpha(X_k) = 1. \tag{14}$$

To further specify (13), write down the coefficients $A_{\nu}$ for $\nu = \nu_k$ as

$$A_{\nu_k} = \left( \frac{1}{\nu_k} \right)^{\frac{\alpha'}{\nu_k}} \frac{1}{\nu_k} \left( \frac{1}{\nu_k} \right)^{\frac{\alpha'}{\nu_k}},$$

so that

$$\log \left( A_{\nu_k}^{\alpha'} \right) = \frac{\alpha'}{\nu_k} \log \frac{1}{\nu_k} - \frac{\alpha'}{\nu_k} \log \frac{1}{\nu_k}.$$

Using $\frac{\alpha'}{\nu_k} = t_k$, one may also write

$$- \log \left( A_{\nu_k}^{\alpha'} \right) = \frac{\alpha'}{\nu_k} \log \frac{1}{\nu_k} - t_k \log t_k + t_k \log \alpha',$$

or equivalently,
which gives
\[ -\sum_{k=1}^{n} \log \left( A_{v_k}^{\alpha'} \right) = \alpha' \sum_{k=1}^{n} \frac{1}{\nu_k} \log \nu_k - \sum_{k=1}^{n} t_k \log t_k + \log \alpha'. \]

To simplify the sum on the right-hand side, first note that
\[ \frac{1}{\nu_k} = 1 - \frac{t_k}{\alpha'}. \]

Hence,
\[
\log B = - \log \left( A_{v_k}^{\alpha'} \right) - \sum_{k=1}^{n} \log \left( A_{v_k}^{\alpha'} \right) \\
= - \log \left( A_{v_k}^{\alpha'} \right) + \log \alpha' - \sum_{k=1}^{n} t_k \log t_k \\
+ \alpha' \sum_{k=1}^{n} \left( 1 - \frac{t_k}{\alpha'} \right) \log \left( 1 - \frac{t_k}{\alpha'} \right).
\]

Choosing in (12) \( t_k = N_\alpha(X_k) \), we thus get
\[
\log N_\alpha(S_n) \geq - \log \left( A_{v_k}^{\alpha'} \right) + \log \alpha' \\
+ \alpha' \sum_{k=1}^{n} \left( 1 - \frac{t_k}{\alpha'} \right) \log \left( 1 - \frac{t_k}{\alpha'} \right).
\]

To bound further the right-hand side, one may apply the elementary inequality \((1 - \varepsilon) \log(1 - \varepsilon) \geq -\varepsilon (0 \leq \varepsilon \leq 1)\), to get
\[
\sum_{k=1}^{n} \left( 1 - \frac{1}{\alpha'} \cdot t_k \right) \log \left( 1 - \frac{t_k}{\alpha'} \right) \geq - \sum_{k=1}^{n} \frac{t_k}{\alpha'} = - \frac{1}{\alpha'},
\]
thus,
\[
\log N_\alpha(S_n) \geq - \log \left( A_{v_k}^{\alpha'} \right) + \log \alpha' - 1.
\]

Finally,
\[
- \log \left( A_{v_k}^{\alpha'} \right) + \log \alpha' = \alpha' \left[ \frac{1}{\alpha'} \log \frac{1}{\alpha'} - \frac{1}{\alpha} \log \frac{1}{\alpha} \right] + \log \alpha' \\
= - \alpha' \log \frac{1}{\alpha} = \frac{1}{\alpha - 1} \log \alpha,
\]
so that
\[
\log N_\alpha(S_n) \geq \frac{1}{\alpha - 1} \log \alpha - 1.
\]

Equivalently,
\[
N_\alpha(S_n) \geq c_\alpha = e^{\frac{1}{\alpha - 1}}.
\]

In view of (14), Theorem I.1 is proved.

V. THE CASE OF THE SHANNON ENTROPY

Let \( X \) and \( Y \) be independent random vectors in \( \mathbb{R}^d \) with absolutely continuous distributions. The following natural question has to be still clarified: Under what assumptions does the entropy power inequality
\[
N(X + Y) \geq N(X) + N(Y) \tag{15}
\]
hold true? In general, the entropy
\[
h(X) = h(p) = - \int_{\mathbb{R}^d} p(x) \log p(x) \, dx,
\]
where \( p \) is density of \( X \), may or may not exist as the Lebesgue integral, and so is the entropy power
\[
N(X) = \exp \left[ \frac{2}{d} h(X) \right].
\]

Hence, at least the existence of \( h(X) \) and \( h(Y) \) has to be postulated in (15), as is done e.g. in [10]. In that case, what can one say about \( h(X + Y) \)?

**Proposition V.1.** For some i.i.d. random vectors \( X \) and \( Y \) in \( \mathbb{R}^d \) the entropy exists, while the entropy of \( X + Y \) does not exist.

Some examples illustrating such a “bad” behaviour with necessarily \( N(X) = N(Y) = 0 \) are described in the next section.

Let us however make the convention that \( N(X) = 0 \), whenever the entropy of \( X \) does not exist, including the cases when the distribution of \( X \) is not absolutely continuous with respect to Lebesgue measure. Then \( N(X) \) is always defined, and the entropy power inequality may indeed be formulated as a universal principle:

**Proposition V.2.** With this convention, the inequality (15) is true for all independent random vectors \( X \) and \( Y \) in \( \mathbb{R}^d \).

For the proof, one can start with Theorem I.1 in the limit case \( \alpha = 1 \), when it becomes
\[
N_1(X + Y) \geq N_1(X) + N_1(Y), \tag{16}
\]
where \( N_1 = \lim_{n \to 1} N_\alpha \). To obtain this inequality for \( N \) in place of \( N_1 \), first we recall an elementary lemma whose proof we include for completeness.

**Lemma V.3.** Let \( X \) be a random vector in \( \mathbb{R}^d \) with density \( p \). If
\[
\int_{\mathbb{R}^d} p^\alpha(x) \, dx < \infty, \text{ for some } \alpha > 1, \tag{17}
\]
then the entropy of \( X \) exists, and \( N_1(X) = N(X) \).

**Proof.** The lemma is a particular case of the following more general assertion. If a random variable \( \xi \geq 0 \) satisfies \( \|\xi\|_r = (E \xi^r)^{1/r} < \infty \), for some \( r > 0 \), then \( E \log \xi \) exists as the Lebesgue integral, and
\[
\|\xi\|_{0^+} = \lim_{r \to 0^+} \|\xi\|_r = \exp\{E \log \xi\}. \tag{18}
\]
To prove the latter, one may assume that \( \xi > 0 \) a.s. First note that the log-moment function \( u(r) = \log E \xi^r \) is continuously differentiable and convex in some interval \( 0 < r < r_0 \). In particular, the derivative \( u'(r) \) is non-decreasing. Since also \( \lim_{r \to 0^+} u(r) = 0 \), we have
\[
\lim_{r \to 0^+} \frac{u(r)}{r} = \lim_{r \to 0^+} \int_0^1 u'(rs) \, ds = \lim_{r \to 0^+} u'(r),
\]
which is exactly the relation (18). It remains to apply it to \( \xi = p(X) \) in which case \( N_\alpha(X) = \|\xi\|_{\alpha - 1} \) (\( \alpha > 1 \)).
If both random vectors $X$ and $Y$ satisfy the integrability condition (17) on their densities, then so does $X + Y$ (by Young’s inequality). Hence, by Lemma V.3, $h(X + Y)$ exists, as well, and $N_1(X + Y) = N(X + Y)$. As a result, we obtain from (16) the entropy power inequality (15) under the condition (17) posed on the summands $X$ and $Y$ (as was stated by Lieb [12]).

It is however desirable to remove the requirement (17), and to this aim a truncation-of-density argument can be used. Given a density $p$ and $n \geq 1$ large enough, define

$$p_n(x) = \frac{1}{c_n} p(x) 1_{\{p(x) \leq n\}}, \quad x \in \mathbb{R}^d,$$

where

$$c_n = \int_{\{p(x) \leq 1\}} p(x) \, dx$$

is a normalizing constant (assuming that $c_n > 0$). If a random vector $X$ has density $p_n$, let us say that $X_n$ has density $p$, truncated at level $n$. By the construction, $p_n$ is bounded, so $h(X_n)$ exists regardless of whether $h(X)$ exists, and we have $-\infty < h(X_n) \leq \infty$.

**Lemma V.4.** Given a random vector $X$ in $\mathbb{R}^d$ with density $p$, let $X_n$ have density $p$, truncated at level $n$. Then, the limit $\lim_{n \to \infty} h(X_n)$ always exists and is equal to $h(X)$, when $h(X)$ exists.

Introduce the positive and negative parts of the entropy of $X$,

$$h^+(X) = \int_{p(x) \leq 1} p(x) \log \frac{1}{p(x)} \, dx$$

and

$$h^-(X) = \int_{p(x) \geq 1} p(x) \log p(x) \, dx.$$

Both integrals are well-defined and non-negative. Moreover, $h(X)$ exists, if and only if $h^+(X) < \infty$ or $h^-(X) < \infty$, in which case

$$h(X) = h^+(X) - h^-(X).$$

An application of the monotone convergence theorem together with the Lebesgue dominated convergence theorem (like in the proof of the next lemma) easily yields

$$\lim_{n \to \infty} h^+(X_n) = h^+(X), \quad \lim_{n \to \infty} h^-(X_n) = h^-(X).$$

To prove Lemma V.4, first note that $c_n \uparrow 1$. Hence, by the very definition,

$$h(X_n) = \frac{\log c_n}{c_n} \int_{p(x) \leq n} p(x) \, dx - \frac{1}{c_n} \int_{p(x) \leq n} p(x) \log p(x) \, dx = o(1) - (1 + o(1)) \int_{p(x) \leq n} p(x) \log p(x) \, dx.$$

The last integral is finite, if and only if $h^+(X)$ is finite. In case $h^+(X) = \infty$, we have $h(X_n) = \infty$, for all $n$. If $h^+(X) < \infty$, then $h(X_n) < \infty$, and moreover,

$$\lim_{n \to \infty} h(X_n) = h^+(X) - \lim_{n \to \infty} \int_{p(x) \leq n} p(x) \log p(x) \, dx = h^+(X) - h^-(X) = h(X).$$

This proves the lemma.

**Lemma V.5.** Given two independent random vectors $X$ and $Y$ in $\mathbb{R}^d$ with densities $p$ and $q$, let $X_n$ and $Y_n$ be independent random vectors in $\mathbb{R}^d$ with densities $p$ and $q$, truncated at levels $n$, respectively. If $h(X + Y)$ exists, then

$$\lim_{n \to \infty} h(X_n + Y_n) = h(X + Y).$$

**Proof.** Denote by $p_n$ and $q_n$ the corresponding truncated densities for $X$ and $Y$ with normalizing constants

$$c_n = \int_{p(x) \leq n} p(x) \, dx, \quad c'_n = \int_{q(x) \leq n} q(x) \, dx.$$

Then $X_n + Y_n$ has a bounded density

$$r_n(x) = (p_n * q_n)(x) = \int_{\mathbb{R}^d} p_n(x - y) q_n(y) \, dy.$$

In particular, the entropy $h(X_n + Y_n)$ exists.

Since $c_n p_n(x) \uparrow p(x)$ and $c'_n q_n(x) \uparrow q(x)$, as $n \to \infty$, we get

$$r_n(x) \to r(x) = (p * q)(x) = \int_{\mathbb{R}^d} p(x - y) q(y) \, dy,$$

which is the density of $Z = X + Y$. Moreover, $c_n c'_n \cdot r_n(x) \uparrow r(x)$, so, by the monotone convergence theorem,

$$\int_{r(x) \geq 1} c_n c'_n \cdot r_n(x) \log (c_n c'_n \cdot r_n(x)) \, dx \uparrow \int_{r(x) \geq 1} r(x) \log r(x) \, dx = h^-(Z).$$

But $c_n c'_n \log (c_n c'_n) \int_{r(x) \geq 1} r_n(x) \, dx \to 0$, and we obtain that

$$\int_{r(x) \geq 1} r_n(x) \log r_n(x) \, dx \to h^-(Z).$$

By a similar argument, using the property that the function $t \log \frac{1}{t}$ is increasing in $0 < t \leq 1/e$, we get that

$$\int_{r(x) \leq 1/e} r_n(x) \log \frac{1}{r_n(x)} \, dx \to \int_{r(x) \leq 1/e} r(x) \log \frac{1}{r(x)} \, dx.$$

Finally, to cover the region $A = \{1/e < r(x) < 1\}$, first note that $\text{mes}(A) \leq e$, in view of $\int r(x) \, dx = 1$. Since the sequence $\tilde{r}_n = c_n c'_n r_n$ is non-decreasing, we have $0 \leq \tilde{r}_n \leq r \leq 1$ on the set $A$, and hence,

$$0 \leq \tilde{r}_n(x) \log \frac{1}{\tilde{r}_n(x)} \leq \frac{1}{e}.$$ 

Consequently, we are in position to apply on $A$ (which has a finite measure) the Lebesgue dominated convergence theorem, which gives

$$\int_A \tilde{r}_n(x) \log \frac{1}{\tilde{r}_n(x)} \, dx \to \int_A r(x) \log \frac{1}{r(x)} \, dx.$$
But the integrals on the left-hand side (as a function of $n$) are convergent or divergent together with $\int_A r_n(x) \log \frac{1}{r_n(x)} \, dx$, while the integral on the right-hand side is finite.

As a result,

$$\int_{r(x)<1} r_n(x) \log \frac{1}{r_n(x)} \, dx \to \int_{r(x)<1} r(x) \log \frac{1}{r(x)} \, dx = h^+(Z).$$

The convergences over the two regions $\{r(x) \geq 1\}$ and $\{r(x) < 1\}$ imply that $h(X_n + Y_n) \to h(Z)$, as long as $h(Z)$ exists. Lemma V.5 is proved. \hfill $\square$

Applying (15) to $X_n$ and $Y_n$ and using the two lemmas, we arrive at the entropy power inequality, where the condition (17) does not appear anymore.

**Corollary V.6.** The entropy power inequality (15) holds true, whenever the entropies of $X$, $Y$, and $X + Y$ exist.

Note that the existence of the entropies is guaranteed, for example, when both $X$ and $Y$ have finite second moments. This is a very popular condition, under which the entropy power inequality is stated. Moreover, it suffices to require that $E\log(1 + |X|) < \infty$ and $E\log(1 + |Y|) < \infty$.

Now, to make the last step towards the more general Proposition V.2, it remains to combine Corollary V.6 with the monotonicity property of the entropy, which we state separately as the following proposition.

**Proposition V.7.** Let $X$ and $Y$ be independent random vectors in $\mathbb{R}^d$. If the entropy of $X$ exists and $N(X) > 0$, then the entropy of $X + Y$ exists as well, and $N(X + Y) \geq N(X)$.

This statement is easily obtained by applying Jensen’s inequality, and we omit the details. Here, it does not matter whether $Y$ has density or not. However, the assumption that $N(X) > 0$ is important, since otherwise the entropy of $X + Y$ may not exist (even if $Y$ has density with well-defined entropy).

What also seems interesting, the monotonicity property does not exclude the cases of a strong “discontinuity” of the entropy under convolutions.

**Proposition V.8.** There exists a random vector $X$ in $\mathbb{R}^d$ with a finite entropy, such that $h(X + Y) = \infty$ for every random vector $Y$ in $\mathbb{R}^d$, which is independent of $X$ and which has a finite entropy.

**VI. Examples**

To illustrate a possible behaviour of the entropy on convolutions, let us start with two examples. For simplicity, we only consider the one-dimensional case.

**Example 1.** For $\varepsilon > 0$, consider probability distributions supported on the interval $(0, \frac{1}{\varepsilon})$ with densities

$$p_{\varepsilon}(x) = \frac{\varepsilon}{x \log(1 + 1/x)}, \quad 0 < x < \frac{1}{\varepsilon}.$$  

The entropy for each of these densities exists, since all $p_{\varepsilon}$ are lower-bounded. Moreover, $h(p_{\varepsilon}) > -\infty$, if and only if $\varepsilon > 1$. The convolution $p_{\varepsilon} * p_{\varepsilon}$ behaves near zero like $p_{2\varepsilon}$, so,

$$h(p_{\varepsilon} * p_{\varepsilon}) > -\infty, \text{ if and only if } \varepsilon > \frac{1}{2}$$  

(cf. e.g. [3]).

**Example 2.** Let a random variable $X$ be uniformly distributed in the set $A$ of Lebesgue measure 1, namely, of the form

$$A = \bigcup_{n=1}^{\infty} (2^n, 2^n + a_n),$$

where $a_n \geq 0$, $\sum_{n=1}^{\infty} a_n = 1$. Then $h(X) = 0$, while, as easy to check,

$$h(X + U) = \frac{1}{2} \sum_{n=1}^{\infty} a_n^2 + \sum_{n=1}^{\infty} a_n \log \frac{1}{a_n},$$

where the random variable $U$ is independent of $X$ and has a uniform distribution in $(0, 1)$. Here, both $X$ and $X + U$ have densities bounded by 1, so there is no need to speak about the existence of the entropies.

This example already shows that in general $h(X + Y)$ cannot be bounded from above in terms of $h(X)$ and $h(Y)$. This is so also in the i.i.d. case, as the next example shows. Moreover, it may occur that $h(X + Y) = \infty$, while the entropy of the summands is finite.

**Example 3.** Let the random variables $X$ and $X'$ be independent with the same uniform density $q = 1_A$ as in the previous example, based on a decreasing sequence $a_n$. Write

$$q = \sum_{n=1}^{\infty} a_n q_n,$$

where $q_n$ is the density of a random variable uniformly distributed in $(2^n, 2^n + a_n)$. Hence,

$$q * q = \sum_{k>n \geq 1} 2 a_k a_n q_k q_n + \sum_{n=1}^{\infty} a_n^2 q_n q_n.$$

The entropy of this convolution exists and is non-negative, since $q * q \leq 1$. To compute it, first note that all densities $q_k * q_{n/k}$ ($k \geq n$) are supported on non-overlapping intervals. On the other hand, if $U_1, U_2$ are independent and uniformly distributed in the intervals of lengths $c_1 \geq c_2 > 0$, then

$$h(U_1 + U_2) = \log c_1 + \frac{c_2}{2c_1}.$$

Using this formula, we find that

$$h(q * q) = -2 \log 2 + 2 \log 2 \sum_{n=1}^{\infty} s_n a_n + \sum_{n=1}^{\infty} \left( n - \frac{1}{2} \right) a_n^2$$

$$+ \sum_{n=1}^{\infty} a_n^2 \log \frac{1}{a_n} + 2 \sum_{n=2}^{\infty} s_{n-1} a_n \log \frac{1}{a_n},$$

where $s_n = a_1 + \cdots + a_n$. Here, since $a_n$ is decreasing and summing to 1, it readily follows that $\sum_{n=1}^{\infty} n a_n^2 \leq 1$. Indeed, necessarily $a_n \leq \frac{1}{n}$, since otherwise, by the monotonicity, we would have $a_k > \frac{1}{2}$ for all $k \leq n$, and then $\sum_{k=1}^{n} a_k > 1$ which contradicts to the assumption. Hence, $\sum_{n=1}^{\infty} (n a_n) a_n \leq \sum_{n=1}^{\infty} a_n = 1$. Next, using $t \log t \leq \frac{1}{2}$
for $0 \leq t \leq 1$, we also have the bound $\sum_{n=1}^{\infty} a_n^2 \log \frac{1}{a_n} \leq \frac{1}{2}$. Therefore,

$$h(q * q) < \infty,$$

if and only if $\sum_{n=1}^{\infty} a_n \log \frac{1}{a_n} < \infty$. (19)

Obviously, in this characterization the assumption on the monotonicity of $a_n$ may be removed.

The cases where $\sum_{n=1}^{\infty} a_n \log \frac{1}{a_n} = \infty$ provide examples proving Proposition V.8. Indeed, using the submodularity property of the entropy (due to Madiman, cf. [13]), for any random variable $Y$, which is independent of $X$ and has finite entropy,

$$h(X + X' + Y) + h(Y) \leq h(X + Y) + h(X' + Y) = 2h(X + Y).$$

But $h(X + X' + Y) \geq h(X + X') = \infty$, according to (19) and Proposition V.7. So it is necessary that $h(X + Y) = \infty$ as well.

**Example 4.** Given $0 < \varepsilon \leq \frac{1}{4}$, let $X$ have the density

$$p = \frac{1}{2} p_e + \frac{1}{2} q,$$

where $q = 1_A$ is the uniform density from Examples 2-3 with $\sum_{n} a_n \log \frac{1}{a_n} = \infty$.

Obviously, the entropy of $X$ exists. More precisely, since $p_e$ and $q$ are supported on disjoint sets, and since $h(q) = 0$,

$$h(X) = \left(\frac{\log 2}{2} + \frac{1}{2} h(p_e)\right) + \left(\frac{\log 2}{2} + \frac{1}{2} h(q)\right) = \log 2 + \frac{1}{2} h(p_e) = -\infty.$$

Now, let $Y$ be an independent copy of $X$, and write the density of $X + Y$ in the form

$$p * p = \frac{1}{4} p_e * p_e + \frac{3}{4} r,$$

where $r = \frac{2}{3} p_e * q + \frac{1}{3} q * q$.

Here, $p_e * p_e$ is supported on $(0, \frac{3}{2})$, while the density $r$ is supported on $(2, \infty)$. Let us show that $h(r) = \infty$, which together with $h(p_e * p_e) = -\infty$ (as in Example 1) would imply that $h(X + Y)$ is not defined, thus proving Proposition V.1.

Note that $p_e * q \leq 1$, which implies $h(p_e * q) \geq 0$. Using the concavity of the function $t \to t \log \frac{1}{t}$, Jensen’s inequality yields

$$h(r) \geq \frac{2}{3} h(p_e * q) + \frac{1}{3} h(q * q) \geq \frac{1}{3} h(q * q) = \infty,$$

according to (19). One may take $\varepsilon = \frac{1}{4}$, for example.

**Example 5.** One can also show that $h(p_e * q) = \infty$, provided that

$$\sum_{n=1}^{\infty} a_n \log \frac{1}{a_n} = \infty, \quad \sum_{n=1}^{\infty} a_n \log^{1-\varepsilon} \frac{1}{a_n} < \infty,$$

where $0 < \varepsilon \leq \frac{1}{4}$. For instance, the choice $a_n \sim \text{const} \cdot \frac{1}{n \log^2 n}$ for large $n$ meets these requirements.

Hence, taking independent random variables $X$ and $Y$ with densities $p$ and $p_e$ as above, we obtain that $h(X) = h(Y) = -\infty$, but $h(X + Y)$ is not defined. In this example, the random variables are not identically distributed, but one of the distributions is compactly supported.

The argument is based on the following estimate: If a random variable $Y$ has the density $p_e$ ($0 < \varepsilon \leq 1$), and $U$ is independent of $Y$ and has a uniform distribution in $(0, 1)$, then for each $0 < a \leq 1/(2\varepsilon)$,

$$h(Y + aU) \geq -C \log^{1-\varepsilon} (1/a),$$

where $C$ is an absolute constant. We leave it for the reader as an exercise.
