Cotonou, 2012
Moving Frames

Classical contributions:

M. Bartels (∼1800), J. Serret, J. Frénet, G. Darboux, É. Cotton, Élie Cartan

Modern developments: (1970’s)

S.S. Chern, M. Green, P. Griffiths, G. Jensen, . . .

The equivariant approach: (1997 – )

Moving Frame — Space Curves

tangent normal binormal
\[
t = \frac{dz}{ds} \quad n = \frac{z_{ss}}{\|z_{ss}\|} \quad b = t \times n
\]

\( s \) — arc length

Frénet–Serret equations
\[
\frac{dt}{ds} = \kappa n \quad \frac{dn}{ds} = -\kappa t + \tau b \quad \frac{db}{ds} = -\tau n
\]

\( \kappa \) — curvature \quad \( \tau \) — torsion
Moving Frame — Space Curves

\[ t = \frac{dz}{ds} \quad n = \frac{z_{ss}}{\|z_{ss}\|} \quad b = t \times n \]

\( s \) — arc length

Frénet–Serret equations

\[ \frac{dt}{ds} = \kappa n \quad \frac{dn}{ds} = -\kappa t + \tau b \quad \frac{db}{ds} = -\tau n \]

\( \kappa \) — curvature \quad \( \tau \) — torsion
“I did not quite understand how he [Cartan] does this in general, though in the examples he gives the procedure is clear.”

“Nevertheless, I must admit I found the book, like most of Cartan’s papers, hard reading.”

— Hermann Weyl

“Cartan on groups and differential geometry”

Applications of Moving Frames

- Differential geometry
- Equivalence
- Symmetry
- Differential invariants
- Rigidity
- Joint invariants and semi-differential invariants
- Invariant differential forms and tensors
- Identities and syzygies
- Classical invariant theory
- Computer vision — object recognition & symmetry detection
- Invariant numerical methods
- Invariant variational problems
- Invariant submanifold flows
- Poisson geometry & solitons
- Killing tensors in relativity
- Invariants of Lie algebras in quantum mechanics
- Lie pseudo-groups
The Basic Equivalence Problem

\( M \) — smooth \( m \)-dimensional manifold.

\( G \) — transformation group acting on \( M \)
  
  - finite-dimensional Lie group
  - infinite-dimensional Lie pseudo-group
**Equivalence:**
Determine when two $p$-dimensional submanifolds $N$ and $\overline{N} \subset M$ are congruent:
\[
\overline{N} = g \cdot N \quad \text{for} \quad g \in G
\]

**Symmetry:**
Find all symmetries, i.e., self-equivalences or self-congruences:
\[
N = g \cdot N
\]
Classical Geometry — F. Klein

- **Euclidean group:** \( G = \begin{cases} 
  \text{SE}(m) = \text{SO}(m) \ltimes \mathbb{R}^m \\
  \text{E}(m) = \text{O}(m) \ltimes \mathbb{R}^m 
\end{cases} \)
  \[
  z \mapsto A \cdot z + b \\
  A \in \text{SO}(m) \text{ or } \text{O}(m), \quad b \in \mathbb{R}^m, \quad z \in \mathbb{R}^m
  \]
  \( \Rightarrow \) isometries: rotations, translations, (reflections)

- **Equi-affine group:** \( G = \text{SA}(m) = \text{SL}(m) \ltimes \mathbb{R}^m \)
  \( A \in \text{SL}(m) \) — volume-preserving

- **Affine group:** \( G = \text{A}(m) = \text{GL}(m) \ltimes \mathbb{R}^m \)
  \( A \in \text{GL}(m) \)

- **Projective group:** \( G = \text{PSL}(m + 1) \)
  acting on \( \mathbb{R}^m \subset \mathbb{R}P^m \)
  \( \Rightarrow \) Applications in computer vision
Tennis, Anyone?
Classical Invariant Theory

Binary form:

\[ Q(x) = \sum_{k=0}^{n} \binom{n}{k} a_k x^k \]

Equivalence of polynomials (binary forms):

\[ Q(x) = (\gamma x + \delta)^n \bar{Q} \left( \frac{\alpha x + \beta}{\gamma x + \delta} \right) \quad g = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in \text{GL}(2) \]

- multiplier representation of \( \text{GL}(2) \)
- modular forms
\[ Q(x) = (\gamma x + \delta)^n \overline{Q} \left( \frac{\alpha x + \beta}{\gamma x + \delta} \right) \]

Transformation group:
\[ g : (x, u) \mapsto \left( \frac{\alpha x + \beta}{\gamma x + \delta}, \frac{u}{(\gamma x + \delta)^n} \right) \]

Equivalence of functions \( \iff \) equivalence of graphs
\[ \Gamma_Q = \{ (x, u) = (x, Q(x)) \} \subset \mathbb{C}^2 \]
Moving Frames

Definition.
A moving frame is a $G$-equivariant map
\[ \rho : M \longrightarrow G \]

Equivariance:
\[ \rho(g \cdot z) = \begin{cases} 
  g \cdot \rho(z) & \text{left moving frame} \\
  \rho(z) \cdot g^{-1} & \text{right moving frame} 
\end{cases} \]

\[ \rho_{\text{left}}(z) = \rho_{\text{right}}(z)^{-1} \]
The Main Result

Theorem. A moving frame exists in a neighborhood of a point $z \in M$ if and only if $G$ acts freely and regularly near $z$. 
Isotropy & Freeness

Isotropy subgroup: \[ G_z = \{ g \mid g \cdot z = z \} \quad \text{for} \quad z \in M \]

- free — the only group element \( g \in G \) which fixes one point \( z \in M \) is the identity
  \[ \implies G_z = \{ e \} \quad \text{for all} \quad z \in M \]

- locally free — the orbits all have the same dimension as \( G \)
  \[ \implies G_z \subset G \text{ is discrete for all} \quad z \in M \]

- regular — the orbits form a regular foliation
  \[ \not\exists \text{ irrational flow on the torus} \]

- effective — the only group element which fixes every point in \( M \) is the identity: \( g \cdot z = z \) for all \( z \in M \) iff \( g = e \):
  \[ G^*_M = \bigcap_{z \in M} G_z = \{ e \} \]
Proof of the Main Theorem

**Necessity:** Let $\rho : M \to G$ be a left moving frame.

**Freeness:** If $g \in G_z$, so $g \cdot z = z$, then by left equivariance:

$$\rho(z) = \rho(g \cdot z) = g \cdot \rho(z).$$

Therefore $g = e$, and hence $G_z = \{e\}$ for all $z \in M$.

**Regularity:** Suppose $z_n = g_n \cdot z \to z$ as $n \to \infty$.

By continuity, $\rho(z_n) = \rho(g_n \cdot z) = g_n \cdot \rho(z) \to \rho(z)$.

Hence $g_n \to e$ in $G$.

**Sufficiency:** By direct construction — “normalization”.

Q.E.D.
Geometric Construction

Normalization = choice of cross-section to the group orbits
Geometric Construction

Normalization = choice of cross-section to the group orbits
Geometric Construction

\[
g = \rho_{\text{left}}(z)
\]

Normalization = choice of cross-section to the group orbits
Geometric Construction

Normalization = choice of cross-section to the group orbits
\[ K \] — cross-section to the group orbits
\[ O_z \] — orbit through \( z \in M \)
\( k \in K \cap O_z \) — unique point in the intersection
  - \( k \) is the canonical form of \( z \)
  - the (nonconstant) coordinates of \( k \) are the fundamental invariants
\( g \in G \) — unique group element mapping \( k \) to \( z \)

\[ \rho(z) = g \quad \text{left moving frame} \quad \rho(h \cdot z) = h \cdot \rho(z) \]

\[ k = \rho^{-1}(z) \cdot z = \rho_{right}(z) \cdot z \]
Algebraic Construction

\[ r = \dim G \leq m = \dim M \]

Coordinate cross-section

\[ K = \{ z_1 = c_1, \ldots , z_r = c_r \} \]

<table>
<thead>
<tr>
<th>left</th>
<th>right</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ w(g, z) = g^{-1} \cdot z ]</td>
<td>[ w(g, z) = g \cdot z ]</td>
</tr>
</tbody>
</table>

\[ g = (g_1, \ldots , g_r) \quad \text{— group parameters} \]

\[ z = (z_1, \ldots , z_m) \quad \text{— coordinates on } M \]
Choose $r = \dim G$ components to \textit{normalize}:

$$w_1(g, z) = c_1 \quad \ldots \quad w_r(g, z) = c_r$$

Solve for the group parameters $g = (g_1, \ldots, g_r)$

$$\Rightarrow \text{ Implicit Function Theorem}$$

The solution

$$g = \rho(z)$$

is a (local) moving frame.
The Fundamental Invariants

Substituting the moving frame formulae

\[ g = \rho(z) \]

into the unnormalized components of \( w(g, z) \) produces the fundamental invariants

\[ I_1(z) = w_{r+1}(\rho(z), z) \quad \ldots \quad I_{m-r}(z) = w_m(\rho(z), z) \]

\[ \implies \] These are the coordinates of the canonical form \( k \in K \).
Completeness of Invariants

Theorem. Every invariant $I(z)$ can be (locally) uniquely written as a function of the fundamental invariants:

$$I(z) = H(I_1(z), \ldots, I_{m-r}(z))$$
Invariantization

Definition. The invariantization of a function $F : M \to \mathbb{R}$ with respect to a right moving frame $g = \rho(z)$ is the invariant function $I = \iota(F)$ defined by

$$I(z) = F(\rho(z) \cdot z).$$

$$\iota(z_1) = c_1, \ldots \iota(z_r) = c_r, \quad \iota(z_{r+1}) = I_1(z), \ldots \iota(z_m) = I_{m-r}(z).$$

cross-section variables fundamental invariants

“phantom invariants”

$$\iota \left[ F(z_1, \ldots, z_m) \right] = F(c_1, \ldots, c_r, I_1(z), \ldots, I_{m-r}(z))$$
Invariantization amounts to restricting $F$ to the cross-section

$$I \mid K = F \mid K$$

and then requiring that $I = \iota(F)$ be constant along the orbits.

In particular, if $I(z)$ is an invariant, then $\iota(I) = I$.

Invariantization defines a canonical projection

$$\iota : \text{functions} \quad \longmapsto \quad \text{invariants}$$
The Rotation Group

\[ G = \text{SO}(2) \quad \text{acting on} \quad \mathbb{R}^2 \]

\[ z = (x, u) \mapsto g \cdot z = (x \cos \phi - u \sin \phi, x \sin \phi + u \cos \phi) \]

\[ \implies \text{Free on} \ M = \mathbb{R}^2 \setminus \{0\} \]

Left moving frame:

\[ w(g, z) = g^{-1} \cdot z = (y, v) \]

\[ y = x \cos \phi + u \sin \phi \quad v = -x \sin \phi + u \cos \phi \]

Cross-section

\[ K = \{u = 0, \ x > 0\} \]
Normalization equation

\[ v = -x \sin \phi + u \cos \phi = 0 \]

Left moving frame:

\[ \phi = \tan^{-1} \frac{u}{x} \implies \phi = \rho(x, u) \in \text{SO}(2) \]

Fundamental invariant

\[ r = \iota(x) = \sqrt{x^2 + u^2} \]

Invariantization

\[ \iota[F(x, u)] = F(r, 0) \]
Prolongation

Most interesting group actions (Euclidean, affine, projective, etc.) are not free!

Freeness typically fails because the dimension of the underlying manifold is not large enough, i.e., $m < r = \dim G$.

Thus, to make the action free, we must increase the dimension of the space via some natural prolongation procedure.

- An effective action can usually be made free by:
• Prolonging to derivatives (jet space)
\[ G^{(n)} : J^n(M, p) \rightarrow J^n(M, p) \]
\[ \Rightarrow \text{differential invariants} \]

• Prolonging to Cartesian product actions
\[ G^{\times n} : M \times \cdots \times M \rightarrow M \times \cdots \times M \]
\[ \Rightarrow \text{joint invariants} \]

• Prolonging to “multi-space”
\[ G^{(n)} : M^{(n)} \rightarrow M^{(n)} \]
\[ \Rightarrow \text{joint or semi-differential invariants} \]
\[ \Rightarrow \text{invariant numerical approximations} \]
Prolonging to derivatives (jet space)

\[ G^{(n)} : J^n(M, p) \longrightarrow J^n(M, p) \]

\[ \implies \text{differential invariants} \]

Prolonging to Cartesian product actions

\[ G^{\times n} : M \times \cdots \times M \longrightarrow M \times \cdots \times M \]

\[ \implies \text{joint invariants} \]

Prolonging to “multi-space”

\[ G^{(n)} : M^{(n)} \longrightarrow M^{(n)} \]

\[ \implies \text{joint or semi-differential invariants} \]

\[ \implies \text{invariant numerical approximations} \]
Euclidean Plane Curves

Special Euclidean group: \( G = \text{SE}(2) = \text{SO}(2) \times \mathbb{R}^2 \)
acts on \( M = \mathbb{R}^2 \) via rigid motions: \( w = R z + b \)

To obtain the classical (left) moving frame we invert the group transformations:
\[
\begin{align*}
y &= \cos \phi (x - a) + \sin \phi (u - b) \\
v &= -\sin \phi (x - a) + \cos \phi (u - b)
\end{align*}
\]

\( w = R^{-1} (z - b) \)

Assume for simplicity the curve is (locally) a graph:
\[
\mathcal{C} = \{ u = f(x) \}
\]

\( \implies \) extensions to parametrized curves are straightforward
Prolong the action to $J^n$ via implicit differentiation:

$$y = \cos \phi (x - a) + \sin \phi (u - b)$$

$$v = -\sin \phi (x - a) + \cos \phi (u - b)$$

$$v_y = \frac{-\sin \phi + u_x \cos \phi}{\cos \phi + u_x \sin \phi}$$

$$v_{yy} = \frac{u_{xx}}{(\cos \phi + u_x \sin \phi)^3}$$

$$v_{yyy} = \frac{(\cos \phi + u_x \sin \phi)u_{xxx} - 3u_{xx}^2 \sin \phi}{(\cos \phi + u_x \sin \phi)^5}$$

...
Prolong the action to $J^n$ via implicit differentiation:

\[
y = \cos \phi (x - a) + \sin \phi (u - b)
\]

\[
v = -\sin \phi (x - a) + \cos \phi (u - b)
\]

\[
v_y = \frac{-\sin \phi + u_x \cos \phi}{\cos \phi + u_x \sin \phi}
\]

\[
v_{yy} = \frac{u_{xx}}{(\cos \phi + u_x \sin \phi)^3}
\]

\[
v_{yyy} = \frac{(\cos \phi + u_x \sin \phi)u_{xxx} - 3u_{xx}^2 \sin \phi}{(\cos \phi + u_x \sin \phi)^5}
\]

\vdots
Normalization: \[ r = \dim G = 3 \]

\[ y = \cos \phi (x - a) + \sin \phi (u - b) = 0 \]

\[ v = -\sin \phi (x - a) + \cos \phi (u - b) = 0 \]

\[ v_y = \frac{-\sin \phi + u_x \cos \phi}{\cos \phi + u_x \sin \phi} = 0 \]

\[ v_{yy} = \frac{u_{xx}}{(\cos \phi + u_x \sin \phi)^3} \]

\[ v_{yyy} = \frac{(\cos \phi + u_x \sin \phi)u_{xxx} - 3u_{xx}^2 \sin \phi}{(\cos \phi + u_x \sin \phi)^5} \]

\[ \vdots \]
Solve for the group parameters:

\[ y = \cos \phi (x - a) + \sin \phi (u - b) = 0 \]
\[ v = -\sin \phi (x - a) + \cos \phi (u - b) = 0 \]
\[ v_y = \frac{-\sin \phi + u_x \cos \phi}{\cos \phi + u_x \sin \phi} = 0 \]

\[ \implies \text{Left moving frame } \rho : J^1 \rightarrow \text{SE}(2) \]
\[ a = x \quad b = u \quad \phi = \tan^{-1} u_x \]
\[ a = x \quad b = u \quad \phi = \tan^{-1} u_x \]

Differential invariants
\[
v_{yy} = \frac{u_{xx}}{(\cos \phi + u_x \sin \phi)^3} \quad \mapsto \quad \kappa = \frac{u_{xx}}{(1 + u_x^2)^{3/2}}
\]
\[
v_{yyy} = \cdots \quad \mapsto \quad \frac{d\kappa}{ds} = \frac{(1 + u_x^2)u_{xxx} - 3u_x u_{xx}^2}{(1 + u_x^2)^3}
\]
\[
v_{yyyy} = \cdots \quad \mapsto \quad \frac{d^2\kappa}{ds^2} - 3\kappa^3 = \cdots
\]
\[ \implies \text{recurrence formulae} \]

Contact invariant one-form — arc length
\[
dy = (\cos \phi + u_x \sin \phi) \, dx \quad \mapsto \quad ds = \sqrt{1 + u_x^2} \, dx
\]
Dual invariant differential operator

\[
\frac{d}{dy} = \frac{1}{\cos \phi + u_x \sin \phi} \frac{d}{dx}
\]

\[
\frac{d}{ds} = \frac{1}{\sqrt{1 + u_x^2}} \frac{d}{dx}
\]

**Theorem.** All differential invariants are functions of the derivatives of curvature with respect to arc length:

\[
\kappa, \quad \frac{d\kappa}{ds}, \quad \frac{d^2\kappa}{ds^2}, \quad \ldots
\]
The Classical Picture:

Moving frame \( \rho : (x, u, u_x) \mapsto (R, a) \in \text{SE}(2) \)

\[
R = \frac{1}{\sqrt{1 + u_x^2}} \begin{pmatrix} 1 & -u_x \\ u_x & 1 \end{pmatrix} = (t, n) \quad a = \begin{pmatrix} x \\ u \end{pmatrix}
\]
Frenet frame

\[ \mathbf{t} = \frac{d\mathbf{x}}{ds} = \left( x_s \right), \quad \mathbf{n} = \mathbf{t}^\perp = \left( -y_s \right). \]

Frenet equations = Pulled-back Maurer–Cartan forms:

\[ \frac{d\mathbf{x}}{ds} = \mathbf{t}, \quad \frac{d\mathbf{t}}{ds} = \kappa \mathbf{n}, \quad \frac{d\mathbf{n}}{ds} = -\kappa \mathbf{t}. \]
Equi-affine Curves \[ G = SA(2) \]

\[ z \mapsto A z + b \quad A \in SL(2), \quad b \in \mathbb{R}^2 \]

Invert for left moving frame:

\[
\begin{align*}
y &= \delta (x - a) - \beta (u - b) \\
v &= -\gamma (x - a) + \alpha (u - b) \\
\alpha \delta - \beta \gamma &= 1
\end{align*}
\]

Prolong to \( J^3 \) via implicit differentiation

\[
dy = (\delta - \beta u_x) \, dx \\
D_y = \frac{1}{\delta - \beta u_x} \, D_x
\]
Prolongation:

\[ y = \delta (x - a) - \beta (u - b) \]

\[ v = -\gamma (x - a) + \alpha (u - b) \]

\[ v_y = -\frac{\gamma - \alpha u_x}{\delta - \beta u_x} \]

\[ v_{yy} = -\frac{u_{xx}}{(\delta - \beta u_x)^3} \]

\[ v_{yyy} = -\frac{(\delta - \beta u_x) u_{xxx} + 3 \beta u_x^2}{(\delta - \beta u_x)^5} \]

\[ v_{yyyy} = -\frac{u_{xxxx} (\delta - \beta u_x)^2 + 10 \beta (\delta - \beta u_x) u_{xx} u_{xxx} + 15 \beta^2 u_{xx}^3}{(\delta - \beta u_x)^7} \]

\[ v_{yyyyy} = \ldots \]
Normalization: \( r = \dim G = 5 \)

\[
\begin{align*}
y &= \delta (x - a) - \beta (u - b) = 0 \\
v &= -\gamma (x - a) + \alpha (u - b) = 0 \\
v_y &= -\frac{\gamma - \alpha u_x}{\delta - \beta u_x} = 0 \\
v_{yy} &= -\frac{u_{xx}}{(\delta - \beta u_x)^3} = 1 \\
v_{yyy} &= -\frac{(\delta - \beta u_x) u_{xxx} + 3 \beta u^2_{xx}}{(\delta - \beta u_x)^5} = 0 \\
v_{yyyy} &= -\frac{u_{xxxx} (\delta - \beta u_x)^2 + 10 \beta (\delta - \beta u_x) u_{xx} u_{xxx} + 15 \beta^2 u_{xx}^3}{(\delta - \beta u_x)^7} \\
v_{yyyyy} &= \ldots
\end{align*}
\]
Equi-affine Moving Frame

\[ \rho : (x, u, u_x, u_{xx}, u_{xxx}) \mapsto (A, b) \in \text{SA}(2) \]

\[
A = \begin{pmatrix}
\alpha & \beta \\
\gamma & \delta \\
\end{pmatrix} = \begin{pmatrix}
\sqrt[3]{u_{xx}} & -\frac{1}{3}u^{-5/3}u_{xxx} \\
u_x\sqrt[3]{u_{xx}} & u^{-1/3} - \frac{1}{3}u^{-5/3}u_{xxx} \\
\end{pmatrix}
\]

\[
b = \begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} x \\ u \end{pmatrix}
\]

Nondegeneracy condition: \( u_{xx} \neq 0 \).

Totally Singular Submanifolds

**Definition.** A $p$-dimensional submanifold $N \subset M$ is **totally singular** if $G^{(n)}$ does not act freely on $j_n N$ for any $n \geq 0$.

**Theorem.** $N$ is totally singular if and only if its symmetry group $G_N = \{ g \mid g \cdot N \subset N \}$ has dimension $> p$, and so $G_N$ does not act freely on $N$ itself.

Thus, the totally singular submanifolds are the only ones that do not admit a moving frame of any order.

In equi-affine geometry, only the straight lines ($u_{xx} \equiv 0$) are totally singular since they admit a three-dimensional equi-affine symmetry group.
Equi-affine arc length

\[ dy = (\delta - \beta u_x) \, dx \quad \mapsto \quad ds = \sqrt[3]{u_{xx}} \, dx \]

Equi-affine curvature

\[ v_{yyyy} \quad \mapsto \quad \kappa = \frac{5 \, u_{xx} \, u_{xxxx} - 3 \, u_{xx}^2}{9 \, u_{xx}^{8/3}} \]
\[ v_{yyyyy} \quad \mapsto \quad \frac{d\kappa}{ds} \]
\[ v_{yyyyyy} \quad \mapsto \quad \frac{d^2\kappa}{ds^2} - 5\kappa^2 \]
The Classical Picture:

\[ A = \begin{pmatrix} \frac{3}{\sqrt[3]{u_{xx}}} & -\frac{1}{3} u^{-5/3} u_{xxx} \\ u_x \frac{3}{\sqrt{u_{xx}}} & u^{-1/3} - \frac{1}{3} u^{-5/3} u_{xxx} \end{pmatrix} = (t, n) \quad b = \begin{pmatrix} x \\ u \end{pmatrix} \]
Frenet frame

\[ t = \frac{dz}{ds}, \quad n = \frac{d^2 z}{ds^2}. \]

Frenet equations = Pulled-back Maurer–Cartan forms:

\[ \frac{dz}{ds} = t, \quad \frac{dt}{ds} = n, \quad \frac{dn}{ds} = \kappa t. \]
Equivalence & Invariants

• Equivalent submanifolds \( N \approx \overline{N} \)
  must have the same invariants: \( I = \overline{I} \).
Equivalence & Invariants

• Equivalent submanifolds \( N \approx \bar{N} \)
must have the same invariants: \( I = \bar{I} \).

Constant invariants provide immediate information:

\[ \text{e.g. } \quad \kappa = 2 \quad \iff \quad \bar{\kappa} = 2 \]
Equivalence & Invariants

- Equivalent submanifolds \( N \approx \bar{N} \)
  must have the same invariants: \( I = \bar{I} \).

Constant invariants provide immediate information:

\[ \text{e.g.} \quad \kappa = 2 \quad \iff \quad \bar{\kappa} = 2 \]

Non-constant invariants are not useful in isolation, because an equivalence map can drastically alter the dependence on the submanifold parameters:

\[ \text{e.g.} \quad \kappa = x^3 \quad \text{versus} \quad \bar{\kappa} = \sinh x \]
However, a functional dependency or syzygy among the invariants is intrinsic:

e.g. \( \kappa_s = \kappa^3 - 1 \iff \bar{\kappa}_\bar{s} = \bar{\kappa}^3 - 1 \)
However, a functional dependency or syzygy among the invariants is intrinsic:

\[ \kappa_s = \kappa^3 - 1 \iff \bar{\kappa}_s = \bar{\kappa}^3 - 1 \]

- Universal syzygies — Gauss–Codazzi
- Distinguishing syzygies.
However, a functional dependency or *syzygy* among the invariants *is* intrinsic:

\[ \kappa_s = \kappa^3 - 1 \iff \overline{\kappa_s} = \overline{\kappa^3} - 1 \]

- Universal syzygies — Gauss–Codazzi
- Distinguishing syzygies.

---

**Theorem.** *(Cartan)* Two submanifolds are (locally) equivalent if and only if they have identical syzygies among *all* their differential invariants.
Finiteness of Generators and Syzygies

♠ There are, in general, an infinite number of differential invariants and hence an infinite number of syzygies must be compared to establish equivalence.

♥ But the higher order syzygies are all consequences of a finite number of low order syzygies!
Example — Plane Curves

If non-constant, both $\kappa$ and $\kappa_s$ depend on a single parameter, and so, locally, are subject to a syzygy:

\[ \kappa_s = H(\kappa) \] (\*)

But then

\[ \kappa_{ss} = \frac{d}{ds} H(\kappa) = H'(\kappa) \kappa_s = H'(\kappa) H(\kappa) \]

and similarly for $\kappa_{sss}$, etc.

Consequently, all the higher order syzygies are generated by the fundamental first order syzygy (\*).

Thus, for Euclidean (or equi-affine or projective or ...) plane curves we need only know a single syzygy between $\kappa$ and $\kappa_s$ in order to establish equivalence!
The Signature Map

The generating syzygies are encoded by the signature map

\[ \Sigma : N \longrightarrow S \]

of the submanifold \( N \), which is parametrized by the fundamental differential invariants:

\[ \Sigma(x) = (I_1(x), \ldots, I_m(x)) \]

The image

\[ S = \text{Im} \, \Sigma \]

is the signature subset (or submanifold) of \( N \).
Equivalence & Signature

Theorem. Two regular submanifolds are equivalent

\[ \overline{N} = g \cdot N \]

if and only if their signatures are identical

\[ \overline{S} = S \]
Signature Curves

Definition. The signature curve $S \subset \mathbb{R}^2$ of a curve $C \subset \mathbb{R}^2$ is parametrized by the two lowest order differential invariants

$$S = \left\{ \left( \kappa, \frac{d\kappa}{ds} \right) \right\} \subset \mathbb{R}^2$$
Other Signatures

Euclidean space curves: $\mathcal{C} \subset \mathbb{R}^3$

$S = \{ (\kappa, \kappa_s, \tau) \} \subset \mathbb{R}^3$

- $\kappa$ — curvature, $\tau$ — torsion

Euclidean surfaces: $S \subset \mathbb{R}^3$ (generic)

$S = \{ (H, K, H_1, H_2, K_1, K_2) \} \subset \mathbb{R}^3$

- $H$ — mean curvature, $K$ — Gauss curvature

Equi–affine surfaces: $S \subset \mathbb{R}^3$ (generic)

$S = \{ (P, P_1, P_2, P_{11}) \} \subset \mathbb{R}^3$

- $P$ — Pick invariant
**Signature Curves**

**Definition.** The *signature curve* $S \subset \mathbb{R}^2$ of a curve $C \subset \mathbb{R}^2$ is parametrized by the two lowest order differential invariants

$$S = \left\{ \left( \kappa, \frac{d\kappa}{ds} \right) \right\} \subset \mathbb{R}^2$$
Signature Curves

Definition. The signature curve $S \subset \mathbb{R}^2$ of a curve $C \subset \mathbb{R}^2$ is parametrized by the two lowest order differential invariants

$$S = \left\{ \left( \kappa, \frac{d\kappa}{ds} \right) \right\} \subset \mathbb{R}^2$$

Theorem. Two regular curves $C$ and $\overline{C}$ are equivalent:

$$\overline{C} = g \cdot C$$

if and only if their signature curves are identical:

$$\overline{S} = S$$
Symmetry and Signature

**Theorem.** The dimension of the symmetry group

\[ G_N = \{ g \mid g \cdot N \subset N \} \]

of a nonsingular submanifold \( N \subset M \) equals the codimension of its signature:

\[ \dim G_N = \dim N - \dim S \]

**Corollary.** For a nonsingular submanifold \( N \subset M \),

\[ 0 \leq \dim G_N \leq \dim N \]

\[ \implies \text{Only totally singular submanifolds can have larger symmetry groups!} \]
Maximally Symmetric Submanifolds

**Theorem.** The following are equivalent:

- The submanifold $N$ has a $p$-dimensional symmetry group
- The signature $\mathcal{S}$ degenerates to a point: $\dim \mathcal{S} = 0$
- The submanifold has all constant differential invariants
- $N = H \cdot \{ z_0 \}$ is the orbit of a $p$-dimensional subgroup $H \subset G$

$\implies$ **Euclidean geometry:** circles, lines, helices, spheres, cylinders, planes, . . .
$\implies$ **Equi-affine plane geometry:** conic sections.
$\implies$ **Projective plane geometry:** $W$ curves (*Lie & Klein*)
Discrete Symmetries

Definition. The index of a submanifold $N$ equals the number of points in $N$ which map to a generic point of its signature:

$$\iota_N = \min \left\{ \# \Sigma^{-1}\{w\} \mid w \in S \right\}$$

$\Rightarrow$ Self–intersections

Theorem. The cardinality of the symmetry group of a submanifold $N$ equals its index $\iota_N$.

$\Rightarrow$ Approximate symmetries
The Index

\[ \Sigma \rightarrow N S \]
The Curve  \( x = \cos t + \frac{1}{5} \cos^2 t, \quad y = \sin t + \frac{1}{10} \sin^2 t \)
The Curve \[ x = \cos t + \frac{1}{5} \cos^2 t, \quad y = \frac{1}{2} x + \sin t + \frac{1}{10} \sin^2 t \]

⇒ Dan Hoff
Classical Invariant Theory

\[ M = \mathbb{R}^2 \setminus \{ u = 0 \} \]

\[ G = \text{GL}(2) = \left\{ \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \mid \Delta = \alpha \delta - \beta \gamma \neq 0 \right\} \]

\[ (x, u) \mapsto \left( \frac{\alpha x + \beta}{\gamma x + \delta} , \frac{u}{(\gamma x + \delta)^n} \right) \quad n \neq 0, 1 \]
Prolongation:

\[ y = \frac{\alpha x + \beta}{\gamma x + \delta} \]

\[ v = \sigma^{-n} u \]

\[ v_y = \frac{\sigma u_x - n \gamma u}{\Delta \sigma^{n-1}} \]

\[ v_{yy} = \frac{\sigma^2 u_{xx} - 2(n - 1)\gamma \sigma u_x + n(n - 1)\gamma^2 u}{\Delta^2 \sigma^{n-2}} \]

\[ v_{yyy} = \ldots \]
Normalization:

\[ y = \frac{\alpha x + \beta}{\gamma x + \delta} = 0 \]

\[ v = \sigma^{-n} u = 1 \]

\[ v_y = \frac{\sigma u_x - n \gamma u}{\Delta \sigma^{n-1}} = 0 \]

\[ v_{yy} = \frac{\sigma^2 u_{xx} - 2(n-1) \gamma \sigma u_x + n(n-1)\gamma^2 u}{\Delta^2 \sigma^{n-2}} = \frac{1}{n(n-1)} \]

\[ v_{yyy} = \ldots \]
Moving frame:
\[
\alpha = u^{(1-n)/n} \sqrt{H} \quad \beta = -x u^{(1-n)/n} \sqrt{H}
\]
\[
\gamma = \frac{1}{n} u^{(1-n)/n} \quad \delta = u^{1/n} - \frac{1}{n} x u^{(1-n)/n}
\]

Hessian:
\[
H = n(n-1)u u_{xx} - (n-1)^2 u_x^2 \neq 0
\]

Note: \( H \equiv 0 \) if and only if \( Q(x) = (a x + b)^n \)
\[\implies \text{Totally singular forms}\]

Differential invariants:
\[
v_{yyy} \mapsto J \approx \kappa \quad v_{yyyy} \mapsto \frac{K + 3(n-2)}{n^3(n-1)} \approx \frac{dk}{ds}
\]
Absolute rational covariants:

\[ J^2 = \frac{T^2}{H^3}, \quad K = \frac{U}{H^2} \]

\[ H = \frac{1}{2}(Q, Q)^{(2)} = n(n-1)QQ'' - (n-1)^2Q'^2 \sim Q_{xx}Q_{yy} - Q_{xy}^2 \]

\[ T = (Q, H)^{(1)} = (2n-4)Q'H - nQH' \sim Q_xH_y - Q_yH_x \]

\[ U = (Q, T)^{(1)} = (3n-6)Q'T - nQT' \sim Q_xT_y - Q_yT_x \]

\[ \text{deg } Q = n \quad \text{deg } H = 2n - 4 \quad \text{deg } T = 3n - 6 \quad \text{deg } U = 4n - 8 \]
Signatures of Binary Forms

Signature curve of a nonsingular binary form $Q(x)$:

$$S_Q = \left\{ (J(x)^2, K(x)) = \left( \frac{T(x)^2}{H(x)^3}, \frac{U(x)}{H(x)^2} \right) \right\}$$

Nonsingular: $H(x) \neq 0$ and $(J'(x), K'(x)) \neq 0$.

Theorem. Two nonsingular binary forms are equivalent if and only if their signature curves are identical.
Maximally Symmetric Binary Forms

**Theorem.** If $u = Q(x)$ is a polynomial, then the following are equivalent:

- $Q(x)$ admits a one-parameter symmetry group
- $T^2$ is a constant multiple of $H^3$
- $Q(x) \simeq x^k$ is complex-equivalent to a monomial
- the signature curve degenerates to a single point
- all the (absolute) differential invariants of $Q$ are constant
- the graph of $Q$ coincides with the orbit of a one-parameter subgroup
Symmetries of Binary Forms

Theorem. The symmetry group of a nonzero binary form $Q(x) \neq 0$ of degree $n$ is:

- A two-parameter group if and only if $H \equiv 0$ if and only if $Q$ is equivalent to a constant. \(\implies\) totally singular
- A one-parameter group if and only if $H \neq 0$ and $T^2 = cH^3$ if and only if $Q$ is complex-equivalent to a monomial $x^k$, with $k \neq 0, n$. \(\implies\) maximally symmetric
- In all other cases, a finite group whose cardinality equals the index of the signature curve, and is bounded by

$$\iota_Q \leq \begin{cases} 6n - 12 & U = cH^2 \\ 4n - 8 & \text{otherwise} \end{cases}$$
Noise Reduction

Strategy #1:

Use lower order invariants to construct a signature:

- joint invariants
- joint differential invariants
- integral invariants
- topological invariants
- ...
Joint Invariants

A joint invariant is an invariant of the $k$-fold Cartesian product action of $G$ on $M \times \cdots \times M$:

$$I(g \cdot z_1, \ldots, g \cdot z_k) = I(z_1, \ldots, z_k)$$

A joint differential invariant or semi-differential invariant is an invariant depending on the derivatives at several points $z_1, \ldots, z_k \in N$ on the submanifold:

$$I(g \cdot z_1^{(n)}, \ldots, g \cdot z_k^{(n)}) = I(z_1^{(n)}, \ldots, z_k^{(n)})$$
Joint Euclidean Invariants

Theorem. Every joint Euclidean invariant is a function of the interpoint distances

\[ d(z_i, z_j) = \| z_i - z_j \| \]
Joint Equi–Affine Invariants

Theorem. Every planar joint equi–affine invariant is a function of the triangular areas

\[
[i \ j \ k] = \frac{1}{2} (z_i - z_j) \wedge (z_i - z_k)
\]
Joint Projective Invariants

Theorem. Every joint projective invariant is a function of the planar cross-ratios

$$[ z_i, z_j, z_k, z_l, z_m ] = \frac{A B}{C D}$$
- Three-point projective joint differential invariant
  — tangent triangle ratio:
  \[
  \begin{bmatrix}
  0 & 2 & 0 \\
  0 & 1 & 1 \\
  1 & 2 & 2 \\
  \end{bmatrix}
  \begin{bmatrix}
  0 & 1 & 0 \\
  1 & 2 & 1 \\
  0 & 2 & 2 \\
  \end{bmatrix}
  \]
Joint Invariant Signatures

If the invariants depend on \( k \) points on a \( p \)-dimensional submanifold, then you need at least

\[
\ell > kp
\]
distinct invariants \( I_1, \ldots, I_\ell \) in order to construct a syzygy. Typically, the number of joint invariants is

\[
\ell = km - r = (#\text{points}) \ (\dim M) - \dim G
\]

Therefore, a purely joint invariant signature requires at least

\[
k \geq \frac{r}{m - p} + 1
\]

points on our \( p \)-dimensional submanifold \( N \subset M \).
Joint Euclidean Signature

\[ z_0 \quad z_1 \]
\[ z_2 \quad z_3 \]

\[ a \quad b \quad c \quad d \quad e \quad f \]
Joint signature map:

\[ \Sigma : \mathbb{C}^4 \rightarrow S \subset \mathbb{R}^6 \]

\[ a = \|z_0 - z_1\| \quad b = \|z_0 - z_2\| \quad c = \|z_0 - z_3\| \]

\[ d = \|z_1 - z_2\| \quad e = \|z_1 - z_3\| \quad f = \|z_2 - z_3\| \]

\[ \Rightarrow \text{six functions of four variables} \]

Syzygies:

\[ \Phi_1(a, b, c, d, e, f) = 0 \quad \Phi_2(a, b, c, d, e, f) = 0 \]

Universal Cayley–Menger syzygy \[\Leftrightarrow\] \[ C \subset \mathbb{R}^2 \]

\[ \det \begin{vmatrix}
2a^2 & a^2 + b^2 - d^2 & a^2 + c^2 - e^2 \\
a^2 + b^2 - d^2 & 2b^2 & b^2 + c^2 - f^2 \\
a^2 + c^2 - e^2 & b^2 + c^2 - f^2 & 2c^2
\end{vmatrix} = 0 \]
Joint Equi–Affine Signature

Requires 7 triangular areas:

\[ 0 1 2 \], \[ 0 1 3 \], \[ 0 1 4 \], \[ 0 1 5 \], \[ 0 2 3 \], \[ 0 2 4 \], \[ 0 2 5 \]
Joint Invariant Signatures

• The joint invariant signature subsumes other signatures, but resides in a higher dimensional space and contains a lot of redundant information.

• Identification of landmarks can significantly reduce the redundancies (Boutin)

• It includes the differential invariant signature and semi-differential invariant signatures as its “coalescent boundaries”.

• Invariant numerical approximations to differential invariants and semi-differential invariants are constructed (using moving frames) near these coalescent boundaries.
Statistical Sampling

Idea: Replace high dimensional joint invariant signatures by increasingly dense point clouds obtained by multiply sampling the original submanifold.

- The equivalence problem requires direct comparison of signature point clouds.
- Continuous symmetry detection relies on determining the underlying dimension of the signature point clouds.
- Discrete symmetry detection relies on determining densities of the signature point clouds.
Symmetry–Preserving Numerical Methods

• Invariant numerical approximations to differential invariants.
• Invariantization of numerical integration methods.

⇒ Structure-preserving algorithms
Numerical approximation to curvature

Heron’s formula

\[ \tilde{\kappa}(A, B, C) = 4 \frac{\Delta}{abc} = 4 \frac{\sqrt{s(s-a)(s-b)(s-c)}}{abc} \]

\[ s = \frac{a + b + c}{2} \quad \text{— semi-perimeter} \]
Invariantization of Numerical Schemes

Suppose we are given a numerical scheme for integrating a differential equation, e.g., a Runge–Kutta Method for ordinary differential equations, or the Crank–Nicolson method for parabolic partial differential equations.

If $G$ is a symmetry group of the differential equation, then one can use an appropriately chosen moving frame to invariantize the numerical scheme, leading to an invariant numerical scheme that preserves the symmetry group. In challenging regimes, the resulting invariantized numerical scheme can, with an inspired choice of moving frame, perform significantly better than its progenitor.
Invariant Runge–Kutta schemes

\[ u_{xx} + x u_x - (x + 1) u = \sin x, \quad u(0) = u_x(0) = 1. \]
Comparison of symmetry reduction and invariantization for

\[ u_{xx} + x u_x - (x + 1)u = \sin x, \quad u(0) = u_x(0) = 1. \]
Invariantization of Crank–Nicolson for Burgers’ Equation

\[ u_t = \varepsilon u_{xx} + u \, u_x \]
The Calculus of Variations

\[ \mathcal{I}[u] = \int L(x, u^{(n)}) \, dx \quad \text{— variational problem} \]

\[ L(x, u^{(n)}) \quad \text{— Lagrangian} \]

To construct the Euler-Lagrange equations: \( \mathbf{E}(L) = 0 \)

- Take the first variation:
  \[ \delta(L \, dx) = \sum_{\alpha,J} \frac{\partial L}{\partial u^\alpha_J} \delta u^\alpha_J \, dx \]

- Integrate by parts:
  \[ \delta(L \, dx) = \sum_{\alpha,J} \frac{\partial L}{\partial u^\alpha_J} D_J(\delta u^\alpha) \, dx \]
  \[ \equiv \sum_{\alpha,J} (-D)^J \frac{\partial L}{\partial u^\alpha_J} \delta u^\alpha \, dx = \sum_{\alpha=1}^{q} \mathbf{E}_\alpha(L) \delta u^\alpha \, dx \]
Invariant Variational Problems

According to Lie, any $G$–invariant variational problem can be written in terms of the differential invariants:

$$\mathcal{I}[u] = \int L(x, u^{(n)}) \, dx = \int P(\ldots \mathcal{D}_K I^\alpha \ldots) \, \omega$$

$I^1, \ldots, I^\ell$ — fundamental differential invariants

$\mathcal{D}_1, \ldots, \mathcal{D}_p$ — invariant differential operators

$\mathcal{D}_K I^\alpha$ — differentiated invariants

$\omega = \omega^1 \wedge \cdots \wedge \omega^p$ — invariant volume form
If the variational problem is $G$-invariant, so

$$I[u] = \int L(x, u^{(n)}) \, dx = \int P(\ldots \mathcal{D}_K I^\alpha \ldots) \, \omega$$

then its Euler–Lagrange equations admit $G$ as a symmetry group, and hence can also be expressed in terms of the differential invariants:

$$\mathbf{E}(L) \simeq F(\ldots \mathcal{D}_K I^\alpha \ldots) = 0$$

Main Problem:

Construct $F$ directly from $P$.

(P. Griffiths, I. Anderson)
Planar Euclidean group \( G = \text{SE}(2) \)

\[
\kappa = \frac{u_{xx}}{(1 + u_x^2)^{3/2}} \quad \text{— curvature (differential invariant)}
\]

\[
ds = \sqrt{1 + u_x^2} \, dx \quad \text{— arc length}
\]

\[
\mathcal{D} = \frac{d}{ds} = \frac{1}{\sqrt{1 + u_x^2}} \frac{d}{dx} \quad \text{— arc length derivative}
\]

Euclidean–invariant variational problem

\[
\mathcal{I}[u] = \int L(x, u^{(n)}) \, dx = \int P(\kappa, \kappa_s, \kappa_{ss}, \ldots) \, ds
\]

Euler-Lagrange equations

\[
\mathbf{E}(L) \simeq F(\kappa, \kappa_s, \kappa_{ss}, \ldots) = 0
\]
Euclidean Curve Examples

Minimal curves (geodesics):

\[ I[u] = \int ds = \int \sqrt{1 + u_x^2} \, dx \]

\[ E(L) = -\kappa = 0 \]

\[ \implies \text{straight lines} \]

The Elastica (Euler):

\[ I[u] = \int \frac{1}{2} \kappa^2 \, ds = \int \frac{u_{xx}^2 \, dx}{(1 + u_x^2)^{5/2}} \]

\[ E(L) = \kappa_{ss} + \frac{1}{2} \kappa^3 = 0 \]

\[ \implies \text{elliptic functions} \]
General Euclidean–invariant variational problem

\[ \mathcal{I}[u] = \int L(x, u^{(n)}) \, dx = \int P(\kappa, \kappa_s, \kappa_{ss}, \ldots) \, ds \]

To construct the invariant Euler-Lagrange equations:

Take the first variation:

\[ \delta(P \, ds) = \sum_j \frac{\partial P}{\partial \kappa_j} \delta\kappa_j \, ds + P \, \delta(ds) \]

Invariant variation of curvature:

\[ \delta\kappa = A_\kappa(\delta u) \quad A_\kappa = D^2 + \kappa^2 \]

Invariant variation of arc length:

\[ \delta(ds) = B(\delta u) \, ds \quad B = -\kappa \]

\[ \implies \text{moving frame recurrence formulae} \]
Integrate by parts:

\[ \delta(P \, ds) \equiv \left[ \mathcal{E}(P) A(\delta u) - \mathcal{H}(P) B(\delta u) \right] ds \]
\[ \equiv \left[ A^* \mathcal{E}(P) - B^* \mathcal{H}(P) \right] \delta u \, ds = \mathbf{E}(L) \, \delta u \, ds \]

Invariantized Euler–Lagrange expression

\[ \mathcal{E}(P) = \sum_{n=0}^{\infty} (-\mathcal{D})^n \frac{\partial P}{\partial \kappa_n} \quad \mathcal{D} = \frac{d}{ds} \]

Invariantized Hamiltonian

\[ \mathcal{H}(P) = \sum_{i>j} \kappa_{i-j} (-\mathcal{D})^j \frac{\partial P}{\partial \kappa_i} - P \]

Euclidean–invariant Euler-Lagrange formula

\[ \mathbf{E}(L) = A^* \mathcal{E}(P) - B^* \mathcal{H}(P) = (\mathcal{D}^2 + \kappa^2) \mathcal{E}(P) + \kappa \mathcal{H}(P) = 0. \]
The Elastica:

\[ I[u] = \int \frac{1}{2} \kappa^2 \, ds \quad P = \frac{1}{2} \kappa^2 \]

\[ \mathcal{E}(P) = \kappa \quad \mathcal{H}(P) = -P = -\frac{1}{2} \kappa^2 \]

\[ \mathbf{E}(L) = (D^2 + \kappa^2) \kappa + \kappa \left( -\frac{1}{2} \kappa^2 \right) = \kappa_{ss} + \frac{1}{2} \kappa^3 = 0 \]
The shape of a Möbius strip

E. L. STAROSTIN AND G. H. M. VAN DER HEIJDEN*
Centre for Nonlinear Dynamics, Department of Civil and Environmental Engineering, University College London, London WC1E 6BT, UK
*e-mail: g.heijden@ucl.ac.uk

Published online: 15 July 2007, doi:10.1038/nmat1928

The Möbius strip, obtained by taking a rectangular strip of plastic or paper, twisting one end through 180°, and then joining the ends, is the canonical example of a one-sided surface. Finding its characteristic developable shape has been an open problem ever since its first formulation in refs 1,2. Here we use the invariant variational bicomplex formalism to derive the first equilibrium equations for a wide developable strip undergoing large deformations, thereby giving the first non-trivial demonstration of the potential of this approach. We then formulate the boundary-value problem for the Möbius strip and solve it numerically. Solutions for increasing width show the formation of creases bounding nearly flat triangular regions, a feature also familiar from fabric draping15 and paper crumpling15. This could give new insight into energy localization phenomena in unstretchable sheets16, which might help to predict points of onset of tearing. It could also aid our understanding of the relationship between geometry and physical properties of nanoscale and microscopic Möbius strip structures15–17.

It is fair to say that the Möbius strip is one of the few icons of mathematics that have been absorbed into wider culture. It has mathematical beauty and inspired artists such as Escher18. In engineering, pulley belts are often used in the form of Möbius strips to wear ‘both’ sides equally. At a much smaller scale, Möbius strips have recently been formed in ribbon-shaped NbSe2 crystals under certain growth conditions involving a large temperature gradient19.

Figure 1 Photo of a paper Möbius strip of aspect ratio 20. The strip adopts a characteristic shape. Inextensibility of the material causes the surface to be developable. Its straight generators are drawn and the colouring varies according to the bending energy density.
Figure 2 Computed Möbius strips. The left panel shows their three-dimensional shapes for \( w = 0.1 \) (a), 0.2 (b), 0.5 (c), 0.8 (d), 1.0 (e) and 1.5 (f), and the right panel the corresponding developments on the plane. The colouring changes according to the local bending energy density, from violet for regions of low bending to red for regions of high bending (scales are individually adjusted). Solution c may be compared with the paper model in Fig. 1 on which the generator field and density colouring have been printed.
Evolution of Invariants and Signatures

$G$ — Lie group acting on $\mathbb{R}^2$

$C(t)$ — parametrized family of plane curves

$G$–invariant curve flow:

$$\frac{dC}{dt} = \mathbf{V} = I \mathbf{t} + J \mathbf{n}$$

- $I, J$ — differential invariants
- $\mathbf{t}$ — “unit tangent”
- $\mathbf{n}$ — “unit normal”

- The tangential component $I \mathbf{t}$ only affects the underlying parametrization of the curve. Thus, we can set $I$ to be anything we like without affecting the curve evolution.
Normal Curve Flows

\[ C_t = J n \]

Examples — Euclidean–invariant curve flows

- \[ C_t = n \] — geometric optics or grassfire flow;
- \[ C_t = \kappa n \] — curve shortening flow;
- \[ C_t = \kappa^{1/3} n \] — equi-affine invariant curve shortening flow:
  \[ C_t = n_{\text{equi-affine}} \]
- \[ C_t = \kappa_s n \] — modified Korteweg–deVries flow;
- \[ C_t = \kappa_{ss} n \] — thermal grooving of metals.
Intrinsic Curve Flows

**Theorem.** The curve flow generated by

\[ \mathbf{v} = I \mathbf{t} + J \mathbf{n} \]

preserves arc length if and only if

\[ \mathcal{B}(J) + \mathcal{D} I = 0. \]

\( \mathcal{D} \) — invariant arc length derivative
\( \mathcal{B} \) — invariant arc length variation

\[ \delta(ds) = \mathcal{B}(\delta u) \, ds \]
Normal Evolution of Differential Invariants

Theorem. Under a normal flow $C_t = J\ n$,

$$\frac{\partial \kappa}{\partial t} = A_\kappa(J), \quad \frac{\partial \kappa_s}{\partial t} = A_{\kappa_s}(J).$$

Invariant variations:

$$\delta \kappa = A_\kappa(\delta u), \quad \delta \kappa_s = A_{\kappa_s}(\delta u).$$

$A_\kappa = A$ — invariant variation of curvature;

$A_{\kappa_s} = D\ A + \kappa\ k_s$ — invariant variation of $\kappa_s$. 
Euclidean–invariant Curve Evolution

Normal flow: \( C_t = J \kappa \)

\[
\frac{\partial \kappa}{\partial t} = \mathcal{A}_\kappa(J) = (D^2 + \kappa^2) J,
\]

\[
\frac{\partial \kappa_s}{\partial t} = \mathcal{A}_{\kappa_s}(J) = (D^3 + \kappa^2D + 3\kappa \kappa_s) J.
\]

**Warning:** For non-intrinsic flows, \( \partial_t \) and \( \partial_s \) do not commute!

---

**Theorem.** Under the curve shortening flow \( C_t = -\kappa \kappa \), the signature curve \( \kappa_s = H(t, \kappa) \) evolves according to the parabolic equation

\[
\frac{\partial H}{\partial t} = H^2 H_{\kappa \kappa} - \kappa^3 H_\kappa + 4\kappa^2 H
\]
Smoothed Ventricle Signature
Intrinsic Evolution of Differential Invariants

Theorem.
Under an arc-length preserving flow,

\[ \kappa_t = \mathcal{R}(J) \quad \text{where} \quad \mathcal{R} = A - \kappa_s D^{-1} B \]  

\[ (*) \]

In surprisingly many situations, (*) is a well-known integrable evolution equation, and \( \mathcal{R} \) is its recursion operator!

\[ \implies \text{Hasimoto} \]
\[ \implies \text{Langer, Singer, Perline} \]
\[ \implies \text{Marí–Beffa, Sanders, Wang} \]
\[ \implies \text{Qu, Chou, Anco, and many more ...} \]
Euclidean plane curves

\[ G = \text{SE}(2) = \text{SO}(2) \times \mathbb{R}^2 \]

\[ A = D^2 + \kappa^2 \quad B = -\kappa \]

\[ R = A - \kappa_s D^{-1} B = D^2 + \kappa^2 + \kappa_s D^{-1} \cdot \kappa \]

\[ \kappa_t = R(\kappa_s) = \kappa_{sss} + \frac{3}{2} \kappa^2 \kappa_s \]

\[ \Longrightarrow \text{modified Korteweg-deVries equation} \]
Equi-affine plane curves

\[ G = \text{SA}(2) = \text{SL}(2) \times \mathbb{R}^2 \]

\[ A = \mathcal{D}^4 + \frac{5}{3} \kappa \mathcal{D}^2 + \frac{5}{3} \kappa_s \mathcal{D} + \frac{1}{3} \kappa_{ss} + \frac{4}{9} \kappa^2 \]

\[ B = \frac{1}{3} \mathcal{D}^2 - \frac{2}{9} \kappa \]

\[ R = A - \kappa_s \mathcal{D}^{-1} B \]

\[ = \mathcal{D}^4 + \frac{5}{3} \kappa \mathcal{D}^2 + \frac{4}{3} \kappa_s \mathcal{D} + \frac{1}{3} \kappa_{ss} + \frac{4}{9} \kappa^2 + \frac{2}{9} \kappa_s \mathcal{D}^{-1} \cdot \kappa \]

\[ \kappa_t = R(\kappa_s) = \kappa_{5s} + \frac{5}{3} \kappa \kappa_{sss} + \frac{5}{3} \kappa_s \kappa_{ss} + \frac{5}{9} \kappa^2 \kappa_s \]

\[ \implies \text{Sawada–Kotera equation} \]

Recursion operator: \[ \widehat{R} = R \cdot (\mathcal{D}^2 + \frac{1}{3} \kappa + \frac{1}{3} \kappa_s \mathcal{D}^{-1}) \]
Euclidean space curves

\[ G = \text{SE}(3) = \text{SO}(3) \ltimes \mathbb{R}^3 \]

\[ A = \begin{pmatrix}
D_s^2 + (\kappa^2 - \tau^2) \\
\frac{2\tau}{\kappa} D_s^2 + \frac{3\kappa \tau_s - 2\kappa_s \tau}{\kappa^2} D_s + \frac{\kappa \tau_{ss} - \kappa_s \tau_s + 2\kappa^3 \tau}{\kappa^2} \\
-2\tau D_s - \tau_s \\
\frac{1}{\kappa} D_s^3 - \frac{\kappa_s}{\kappa^2} D_s^2 + \frac{\kappa^2 - \tau^2}{\kappa} D_s + \frac{\kappa_s \tau^2 - 2\kappa \tau \tau_s}{\kappa^2}
\end{pmatrix} \]

\[ B = \begin{pmatrix} \kappa \\ 0 \end{pmatrix} \]

\[ \mathcal{R} = A - \left( \begin{pmatrix} \kappa_s \\ \tau_s \end{pmatrix} \right) D^{-1} B \]

\[ \begin{pmatrix} \kappa_t \\ \tau_t \end{pmatrix} = \mathcal{R} \begin{pmatrix} \kappa_s \\ \tau_s \end{pmatrix} \]

\[ \implies \text{vortex filament flow (Hasimoto)} \]
The Recurrence Formula

For any function or differential form $\Omega$:

\[
d\iota(\Omega) = \iota(d \Omega) + \sum_{k=1}^{r} \nu^k \wedge \iota[v_k(\Omega)]
\]

$v_1, \ldots, v_r$ — basis for $\mathfrak{g}$ — infinitesimal generators

$\nu^1, \ldots, \nu^r$ — dual invariantized Maurer–Cartan forms

★ ★ The $\nu^k$ are uniquely determined by the recurrence formulae for the phantom differential invariants
\[
d\iota(\Omega) = \iota(d\Omega) + \sum_{k=1}^{r} \nu^k \wedge \iota[v_k(\Omega)]
\]

★★★★ All identities, commutation formulae, syzygies, etc., among differential invariants and, more generally, the invariant variational bicomplex follow from this universal recurrence formula by letting \( \Omega \) range over the basic functions and differential forms!
\[
d d \iota(\Omega) = \iota(d\Omega) + \sum_{k=1}^{r} \nu^k \wedge \iota[v_k(\Omega)]
\]

★★★ All identities, commutation formulae, syzygies, etc., among differential invariants and, more generally, the invariant variational bicomplex follow from this universal recurrence formula by letting \( \Omega \) range over the basic functions and differential forms!

★★★ Therefore, the entire structure of the differential invariant algebra and invariant variational bicomplex can be completely determined using only linear differential algebra; this does not require explicit formulas for the moving frame, the differential invariants, the invariant differential forms, or the group transformations!
The Basis Theorem

**Theorem.** The differential invariant algebra \( \mathcal{I} \) is generated by a finite number of differential invariants

\[
I_1, \ldots, I_\ell
\]

and \( p = \text{dim} \, N \) invariant differential operators

\[
\mathcal{D}_1, \ldots, \mathcal{D}_p
\]

meaning that every differential invariant can be locally expressed as a function of the generating invariants and their invariant derivatives:

\[
\mathcal{D}_j I_\kappa = \mathcal{D}_{j_1} \mathcal{D}_{j_2} \cdots \mathcal{D}_{j_n} I_\kappa.
\]

\[\Rightarrow \quad \text{Lie, Tresse, Ovsiannikov, Kumpera}\]

\[\star \quad \text{Moving frames provides a constructive proof.}\]
Minimal Generating Invariants

A set of differential invariants is a generating system if all other differential invariants can be written in terms of them and their invariant derivatives.

Euclidean curves $C \subset \mathbb{R}^3$:
- curvature $\kappa$ and torsion $\tau$

Equi-affine curves $C \subset \mathbb{R}^3$:
- affine curvature $\kappa$ and torsion $\tau$

Euclidean surfaces $S \subset \mathbb{R}^3$:
- mean curvature $H$
  - Gauss curvature $K = \Phi(\mathcal{D}^{(4)}H)$.

Equi-affine surfaces $S \subset \mathbb{R}^3$:
- Pick invariant $P$.
