Cyclic Sieving

Definition ([RSW04])
Suppose the cyclic group $C_n = \langle r \rangle$ acts on a finite set $X$, and $X(q)$ is a polynomial in $q$. The pair $(X \otimes C_n, X(q))$ has the cyclic sieving phenomenon (CSP) if, for all $t \in \mathbb{N}$,
\[
|\{x \in X : r^t x = x\}| = X(e^{2\pi i t/n}).
\]

Equivalently, the number of points fixed by $r^t \in C_n$ can be computed by evaluating a certain polynomial at an appropriate $n$th root of unity. Think of this as the eigenvalue of $r^t$ in the representation of $C_n$ which sends $r$ to a $1/n$-th root on $C$. This point of view allows us to generalize sieving to any group.

Sieving Phenomena for any Group

Definition
Suppose a group $G$ acts on a finite set $X$, and $X(q)$ is a symmetric polynomial in $d$ variables with $\rho$ a $d$-dimensional representation of $G$. The pair $(X \otimes G, \rho, X(q))$ exhibits $G$-sieving if, for all $g \in G$, if $\lambda_1, \lambda_2, \ldots, \lambda_d$ are the eigenvalues of $\rho(g)$, then
\[
|\{x \in X : gx = x\}| = X(\lambda_1, \lambda_2, \ldots, \lambda_d).
\]

In the case of the dihedral group $D(n) := \langle r, s \rangle$ with $r^n = s^2 = 1$, $rs = sr^{-1}$, we use the representation $\rho_{rs}$ which sends $r$ to a rotation by $2\pi/n$ radians and $s$ to a reflection about the x-axis.

Odd Dihedral Sieving

Definition (cf. [RS17, Proposition 4.3])
Suppose the dihedral group $D(n)$ acts on a set $X$, and $X(q)$ is a symmetric polynomial in $q$ and $t$. The pair $(X \otimes D(n), X(q))$ has the dihedral sieving phenomenon (DSP) if, for all $g \in D(n)$ with eigenvalues $\{\lambda_1, \lambda_2\}$ for $\rho_{rs}(g)$,
\[
|\{x \in X : gx = x\}| = X(\lambda_1, \lambda_2).
\]

Rao and Suk [RS17] found many examples of odd dihedral sieving using a different, but equivalent definition.

Acknowledgements

This research was performed at the University of Minnesota–Twin Cities REU with the support of NSF grant DMS-1148834. We are extremely grateful to Vic Reiner for his guidance and support throughout the course of this project, and would like to thank Sarah Brauner and Andy Hardt for their insightful feedback. We also thank Christopher Ryba for a helpful discussion about his proof of one of our conjectures.

Raney Numbers

To prove an instance of dihedral sieving, we usually count the number of elements of the set $X$ fixed by each dihedral group element combinatorially, and check that the result matches with the evaluation of the polynomial. In most cases, cyclic sieving results of Eu and Fu [EF08] allow us to focus on the group elements representing reflections. A nice bijection with coralt diagrams allows us to show that the number of $k$-angulations which share a certain axis of symmetry is a certain Raney number. The Raney numbers are defined as
\[
R_{r/k} := \frac{r}{kp + r} \sum_{m \in \mathbb{N}} \frac{1}{k}.
\]

Interestingly, these numbers specialize to the Fuss–Catalan numbers when $r = 1$, and the usual Catalan numbers when $(p, r) = (2, 1)$. In this case, evaluating the polynomial turned out to be the trickier part. We needed to show:
\[
\text{Cat}_{ms + 1, m}(-1) := \sum_{q \in \mathbb{N}} \frac{1}{q}\binom{q}{m} = \left(\frac{m - 1}{2}\right).
\]

Here the sum is over all Dyck paths $P$ connecting $(0, 0)$ to $(ms + 1, m)$ while staying above the non-main diagonal, as pictured below.

Young diagram for $m = 5$ and $s = 3$, with an area cut out by a Dyck path.

The proof of this equality led us to discover an interesting determinant identity and rediscover some recursions on Raney numbers.

Future Work

1. We generalized dihedral sieving for triangulations in two directions: first by introducing the Fuss parameter, and second by considering other types. One could hope to prove a single unifying result by showing dihedral sieving for non-maximal clusters of arbitrary type. Unfortunately, the properties of the $(p, r)$-Fuss–Catalan polynomials are still quite conjectural in types other than $A$, and the objects in question only get harder to work with. Other potential sets to look at for dihedral sieving include $k$-divisible dissections and the rational associahedron.

2. Our results apply only to the case of odd $n$, because the representation theory of $D(n)$ is more complicated when $n$ is even. In particular, there is an additional conjugacy class, which gives rise to additional irreducible representations. We have some ideas for how to deal with these challenges, but more work is needed to determine whether a natural notion of dihedral sieving even exists for $n$ even.

3. Though it is not discussed in this poster, we have also introduced the sieving phenomenon for the symmetric group, and shown an instance of symmetric sieving for multisets with complete homogeneous polynomials. We also gave a conjecture about symmetric sieving for subsets, using Schur polynomials, which was subsequently proven by Christopher Ryba. It would be very interesting to see more examples of symmetric sieving.
