Lecture 19: Quick review from previous lecture • If $p \ge 1$, we define:

$$\|\mathbf{x}\|_p = \left(\sum_{i=1}^n |x_i|^p\right)^{1/p}$$

This is often called the p **norm**.

• We define the L^p norms on $C^0([a, b])$, for $p \ge 1$:

$$||f||_p = \left(\int_a^b |f(x)|^p dx\right)^{1/p}$$

• If A is any n-by-n matrix, then

$$||A|| = \max\{||A\mathbf{u}|| : ||\mathbf{u}|| = 1\}$$

Today we will discuss Positive definite matrix.

Jesse(TA): No office hours on March 17th (Tues.) and March 19th. Instead, March 24 (Tues.) and March 26 (Thur.) from 8:05 am to 12:05 pm

 Quiz 4 (covers sec. 2.5, 3.1, 3.2) will take place in the beginning of the class on Friday 3/20

3.4 - 3.5 Positive Definite Matrices

Definition: An $n \times n$ matrix K is called **positive definite** if it is symmetric, $K^T = K$, and satisfies the positivity condition

$$\mathbf{\mathbf{x}}^T K \mathbf{\mathbf{x}} > 0 \qquad \text{for all } \mathbf{0} \neq \mathbf{x} \in \mathbb{R}^n.$$

We write K > 0 to mean that K is positive definite matrix.

Note: for a matrix A, the function

$q(\mathbf{x}) = \mathbf{x}^T A \mathbf{x}$

is called a quadratic form. "quadratic form is called positive definite Warning: positive definite matrices may have negative entries, while entries with

Warning: positive definite matrices may have negative entries, while entries with all positive entries may not always be positive definite. $\times \quad \underbrace{< \mathcal{R}}_{\diamond}$

$$K = \left(\begin{array}{cc} 4 & -2 \\ -2 & 3 \end{array}\right)$$

is positive definite, but it has negative entries.

$$q(\mathbf{x}) = \mathbf{x}^{\mathsf{T}} \mathbf{K} \mathbf{x} = (\mathbf{x}, \mathbf{x}_{2}) \begin{pmatrix} \mathbf{x}_{1} \\ -\mathbf{z} \end{pmatrix} \begin{pmatrix} \mathbf{x}_{1} \\ \mathbf{x}_{2} \end{pmatrix}$$
$$= \underbrace{\mathbf{x}_{1}^{\mathsf{T}} - \mathbf{x}_{1} \mathbf{x}_{2}}{\mathbf{x}_{1}^{\mathsf{T}} - \mathbf{x}_{1} \mathbf{x}_{2}} + \underbrace{\mathbf{x}_{2}^{\mathsf{T}}}{\mathbf{x}_{2}^{\mathsf{T}} - \mathbf{x}_{2}^{\mathsf{T}}}$$
$$= \underbrace{(\mathbf{x}_{1}^{\mathsf{T}} - \mathbf{x}_{1} \mathbf{x}_{2} + \mathbf{x}_{2}^{\mathsf{T}}) + \mathbf{x}_{2}^{\mathsf{T}} - \mathbf{x}_{2}^{\mathsf{T}}}{\mathbf{x}_{2}^{\mathsf{T}} - \mathbf{x}_{2}^{\mathsf{T}}}$$
$$= \underbrace{(\mathbf{x}_{1}^{\mathsf{T}} - \mathbf{x}_{1} \mathbf{x}_{2} + \mathbf{x}_{2}^{\mathsf{T}}) + \mathbf{x}_{2}^{\mathsf{T}} - \mathbf{x}_{2}^{\mathsf{T}}}{\mathbf{x}_{2}^{\mathsf{T}} - \mathbf{x}_{2}^{\mathsf{T}}}$$
$$= \underbrace{(\mathbf{x}_{1}^{\mathsf{T}} - \mathbf{x}_{2})^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}} - \mathbf{x}_{2}^{\mathsf{T}}}{\mathbf{x}_{2}^{\mathsf{T}} - \mathbf{x}_{2}^{\mathsf{T}}}$$
$$= \underbrace{(\mathbf{x}_{1}^{\mathsf{T}} - \mathbf{x}_{2})^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}} - \mathbf{x}_{2}^{\mathsf{T}}}{\mathbf{x}_{2}^{\mathsf{T}} - \mathbf{x}_{2}^{\mathsf{T}}}$$
$$= \underbrace{(\mathbf{x}_{1}^{\mathsf{T}} - \mathbf{x}_{2})^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}}} - \mathbf{x}_{2}^{\mathsf{T}}}{\mathbf{x}_{2}^{\mathsf{T}} + \mathbf{x}_{2}^{\mathsf{T}} +$$

$$\mathcal{G}(\mathbf{x}) = \mathbf{x}^{\mathsf{T}} \mathbf{A} \mathbf{x} = \mathbf{x}_{1}^{\mathsf{Z}} + 6\mathbf{x}_{2}\mathbf{x}_{1} + 2\mathbf{x}_{2}^{\mathsf{Z}}$$

Taking
$$X_{0} = (1, -1)^{T}$$
, $q(X_{0}) = -3 < 0$

A is NOT portile

How can we tell if a matrix K is positive definite? We obviously can't evaluate $\mathbf{x}^T K \mathbf{x}$ for all vectors \mathbf{x} !

§ The positive definite 2×2 matrices.

Take any symmetric 2-by-2 matrix A:

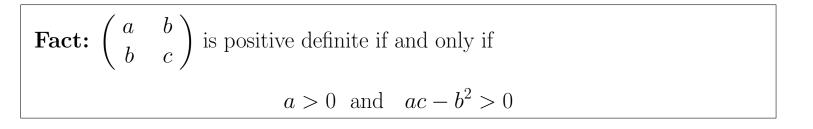

$$A = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$$

$$g(x) = (x_1, x_2) \begin{pmatrix} a & b \\ b & c \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = ax_1^2 + 2bx_1x_2 + (x_2^2)$$
(1) $a \leq 0$, then A is NOT positive definite.

$$F = A = \begin{pmatrix} -3 & b \\ b & c \end{pmatrix}, \quad e_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad q(e_1) = e_1^T A e_1 = -3 < 0$$
Thus, we suppose $a > 0$.
(2) Complete the square:

$$g(x) = (\sqrt{a} \times 1 + \frac{b}{\sqrt{a}} \times 2)^2 + (c - \frac{b^2}{a}) \times 2^2$$

$$g(x) > 0 \quad if \quad (c - \frac{b^2}{a} > 0) \begin{pmatrix} a - b^2 > 0 \\ c - b^2 > 0 \end{pmatrix}$$

§ The positive definite $n \times n$ matrices.

Is there a simple characterization for positive definite matrices of any size? Recall: Any regular symmetric matrix A can be factored in the form

$$A \xrightarrow{Gaussian} \bigcup = \begin{pmatrix} u_{11} \\ \vdots \\ \vdots \\ \vdots \\ u_{nn} \end{pmatrix}, \begin{array}{c} u_{11} \neq 0, \dots, u_{nn} \neq 0 \\ A = LDL^{T}, \\ \end{array}$$

where L is lower unitriangular and D is diagonal.

(*This factorization is computed via Gaussian elimination.)

- **1.** 2×2 symmetric matrix Suppose $A = \begin{pmatrix} a & b \\ b & c \end{pmatrix}$.
 - a > 0, B_{y} Gaussian Elmination, $A \xrightarrow{(2) - \frac{b}{a}0}_{U^{=}} \begin{pmatrix} a & b \\ o & c - \frac{b^{2}}{a} \end{pmatrix}$, $L = \begin{pmatrix} l & 0 \\ \frac{b}{a} & l \end{pmatrix}$.

$$= \bigsqcup_{i=1}^{n} = \begin{pmatrix} 1 & 0 \\ \frac{b}{a} & 1 \end{pmatrix} \begin{pmatrix} a & b \\ 0 & c - \frac{b^{2}}{a} \end{pmatrix}.$$
$$= \begin{pmatrix} 1 & 0 \\ \frac{b}{a} & 1 \end{pmatrix} \begin{pmatrix} a & 0 \\ 0 & c - \frac{b^{2}}{a} \end{pmatrix} \begin{pmatrix} 1 & \frac{b}{a} \\ 0 & 1 \end{pmatrix}$$
$$= \underbrace{L} \qquad D \qquad L^{T}$$

2. Any size symmetric matrix

It turns out that this same criterion characterizes positive definite matrices of any size.

Fact: An n-by-n matrix A is positive definite if and only if it is:

- (a) symmetric;
- (b) regular, hence $A = LDL^T$; and
- (c) D has all positive diagonal entries, i.e. A has positive pivots.

Fact: If a matrix is positive definite, then it is nonsingular.

Example. Suppose A is the symmetric matrix

$$A = \begin{pmatrix} 1 & 1 & -1 \\ 1 & 1 & 0 \\ -1 & 0 & 2 \end{pmatrix}$$

Example. Suppose A is the symmetric matrix

Example. Suppose A is the symmetric matrix

$$A = \begin{pmatrix} 1 & -1 & 2 \\ -1 & 2 & -3 \\ 2 & -3 & 7 \end{pmatrix}$$

$$(1 & 0 & 0 \\ -1 & 1 & 0 \\ 2 & -1 & 1 \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 0 & 0 & 2 \\ 0 & 0 & 2 \end{pmatrix} \begin{pmatrix} 1 & -1 & 2 \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix}$$

$$L \qquad D \qquad L^{T}$$

$$Thus \qquad A > 0 \qquad \not >$$

Definition: If a matrix A satisfies $\mathbf{x}^T A \mathbf{x} \ge 0$ for all vectors \mathbf{x} , it is called **positive semidefinite**.

Remark: Every positive definite matrix is also positive semidefinite; but the converse is not true, since a positive semidefinite matrix A might have $\mathbf{x}^T A \mathbf{x} = 0$ for $\mathbf{x} \neq \mathbf{0}$.

Example. The matrix $A = \begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}$ is positive semidefinite, but not positive definite. $\chi^{T}A \times$ $Q(x) = A = X_{1}^{2} - 2X_{1}X_{2} + X_{2}^{2} = (X_{1} - X_{2})^{2} \ge O$. Th = A is positive semidefinite. $Q(x) = O \iff X_{1} = X_{2}$. $S_{0} = A$ is <u>MOT</u> positive definite.

Definitions:

- a matrix A is **negative definite** if $\mathbf{x}^T A \mathbf{x} < 0$ for all $\mathbf{x} \neq \mathbf{0}$.
- Similarly, a matrix A is **negative semidefinite** if $\mathbf{x}^T A \mathbf{x} \leq 0$ for all \mathbf{x} .
- If a matrix is neither positive or negative semidefinite, it is called **indefinite**. This means that there are vectors \mathbf{x} and \mathbf{y} with $\mathbf{x}^T A \mathbf{x} > 0$ and $\mathbf{y}^T A \mathbf{y} < 0$.

*Only "positive definite" matrices define inner products, via $\langle \mathbf{x}, \mathbf{y} \rangle = \mathbf{x}^T A \mathbf{y}$.
